Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR74 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 BANKSPLT_EN	Enables bank splitting as a condition when using the placement logic to fill the command queue. 0 Disable 1 Enable
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ADDR_CMP_EN	Enables address collision/data coherency detection as a condition when using the placement logic to fill the command queue. 0 Diasble 1 Enable

Table continues on the next page...

DDRMC_CR74 field descriptions (continued)

Field	Description
15–8 CMD_AGE_CNT	Holds the initial value of the command aging counters associated with each command in the command queue. When using the placement logic to fill the command queue, the command aging counters decrement one each time the master aging-rate counter counts down the number of cycles in the age_count parameter. This parameter is only applicable when priority is enabled as a placement factor (the parameter is set to 1).
7–0 AGE_CNT	Holds the initial value of the master aging-rate counter. This parameter is only applicable when priority is enabled as a placement factor

34.5.76 Control Register 75 (DDRMC_CR75)

Address: 400A_E000h base + 12Ch offset = 400A_E12Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_CR75 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RW_PG_EN	Enables page grouping within a read/ write group as a condition when using the placement logic to fill the command queue. 0 Disable 1 Enable
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 RW_EN	Enables read/write grouping as a condition when using the placement logic to fill the command queue. 0 Disable 1 Enable
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR75 field descriptions (continued)

Field	Description
8 PRI_EN	Enables priority as a condition when using the placement logic to fill the command queue. 0 Disable 1 Enable
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 PLEN	Enables using the placement logic to fill the command queue. 0 Disable placement logic. The command queue is a straight FIFO. 1 Enable placement logic. The command queue will be filled according to the placement logic factors.

34.5.77 Control Register 76 (DDRMC_CR76)

Address: 400A_E000h base + 130h offset = 400A_E130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0					NQENT_ACTDIS			0						D_RW_G_BKCN

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR76 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 NQENT_ACTDIS	Specifies the number of entries of the command queue in which ACT requests are not allowed. For this 8-deep command queue, the entries are numbered 0-7, where entry 0 is the command next to execute. • 0x0 = ACT allowed from entries 0-7 • 0x1 = ACT allowed from entries 0-6 • 0x2 = ACT allowed from entries 0-5 • 0x3 = ACT allowed from entries 0-4 • 0x4 = ACT allowed from entries 0-3 • 0x5 = ACT allowed from entries 0-2

Table continues on the next page...

DDRMC_CR76 field descriptions (continued)

Field	Description
	• 0x6 = ACT allowed from entries 0-1 • 0x7 = ACT allowed from entry 0
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 D_RW_G_BKCN	Enables read/write grouping as a condition when using the placement logic to fill the command queue. • Bit [1] = Prohibits placement into a command queue entry 2 entries away (before or after) from a command with a bank conflict. • 0 — Allowed • 1 — Prohibited • Bit [0] = Prohibits placement into a command queue entry immediately before or immediately after a command with a bank conflict. • 0 — Allowed • 1 — Prohibited **NOTE:** It is not meaningful to set bit [1] of this parameter without setting bit [0].
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 W2R_SPLT_EN	Enables write-to-read turnaround time optimization for commands to the same chip select as a condition when using the placement logic to fill the command queue. When this parameter is set to 1, the placement logic will attempt to place commands between two entries that are accessing the same chip select, but are different types, and where the write is going to execute before the read. 0 Disable 1 Enable
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CS_EN	Enables rank grouping within a R/W group as a condition when using the placement logic to fill the command queue. If the rw_same_en parameter is set to 1, the placement logic will try to group commands of the same type and same rank when possible. If there are no rank grouping opportunities, the logic will still attempt to group commands of the same type. If the rw_same_en parameter is cleared to 0, this parameter has no effect. 0 Disable 1 Enable

34.5.78 Control Register 77 (DDRMC_CR77)

Address: 400A_E000h base + 134h offset = 400A_E134h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_CR77 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CS_MAP	Set this bit to enable the CS
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 IN_DRAM_CMD	Inhibits certain types of commands from being executed from the command queue. Even when this parameter is programmed to a non-zero value, commands may still be accepted into the memory controller and the core command queue, but they will not be executed. • 00 = Enable any command in the command to execute. • 01 = Inhibit read/write traffic and associated bank commands in the command queue from being executed. • 10 = Inhibit MRR and peripheral MRR commands from being executed. • 11 = Inhibit MRR commands and read/write commands in the command queue from being executed. The MRR settings are only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = ’b0101)
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 DI_RD_ INTLEAVE	Disables read data interleaving for commands from the same port, regardless of the requestor ID. Read data may still be returned out of order regardless of the value of this parameter. 0 Allow read data interleaving 1 Disable read data interleaving

Table continues on the next page...

DDRMC_CR77 field descriptions (continued)

Field	Description
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 SWAP_EN	Enables swapping of the active command for a new higher-priority command when using the placement logic. 0 Disable 1 Enable

34.5.79 Control Register 78 (DDRMC_CR78)

Address: 400A_E000h base + 138h offset = 400A_E138h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR78 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 Q_FULLNESS	Defines quantity of data that will be considered full for the command queue.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 LPDDR2_S4	Indicates the type of LPDDR2 memory(s) being used. The user must manually set this bit for LPDDR2-S4 memory(s). • 0 = LPDDR2-S2 memory in the system • 1 = LPDDR2-S4 memory in the system This parameter is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = 'b0101)
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR78 field descriptions (continued)

Field	Description
8 REDUC	Allows the same memory controller to be used with memories with a smaller datapath. When enabled, certain bits of the PHY data bus are unused since the memory data bus is half the width of the initial configured size. **NOTE:** The entire user datapath is used regardless of this setting. **NOTE:** This parameter should not be changed after the start parameter has been set to 1. • 0 = Standard operation using full memory bus. • 1 = Memory datapath width is half of the maximum size.
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 BUR_ON_FLY_BIT	Defines the bit of the DRAM address that defines Burst-On-Fly behavior. The memory controller does not support burst-on-fly behavior at this time. However, this parameter must be programmed to ’b1100 for accurate system operation as defined by the JEDEC specification. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)

34.5.80 Control Register 79 (DDRMC_CR79)

Address: 400A_E000h base + 13Ch offset = 400A_E13Ch

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR79 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CTLUPD_AREF	Enables an automatic controller-initiated update after every refresh. 0 Disable 1 Enable
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR79 field descriptions (continued)

Field	Description
16 CTLUPD_REQ	Triggers a controller-initiated update request on the PHY interface. This parameter is write-only and will always read back as 0x0. **NOTE:** For proper operation, the user must issue at least one read or write command to memory after reset prior to setting this parameter. 0 No action 1 Trigger a controller-initiate update request
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 CTLBUSY	Indicates that the memory controller is actively processing a command from any port. This information is also passed to the ASIC through the controller_busy signal. This parameter is read-only. 0 MC is not busy 1 MC is busy
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 INODR_ACT	Forces the controller to accept commands in the order in which they are placed in the command queue.

34.5.81 Control Register 80 (DDRMC_CR80)

Address: 400A_E000h base + 140h offset = 400A_E140h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR80 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–0 INT_STAT	Shows the status of all possible interrupts generated by the controller. **NOTE:** If possible, the location of the int_stat parameter has been preserved from the previous delivery. However, the individual bits, their meaning and the size of the parameter may have changed. The int_stat bits correspond to these interrupts: • Bit [28] = Logical OR of all lower bits. • Bit [27] = The frequency change hardware has completed all operations. The system will hold off normal operations if the FRQ_CHG_HOEN parameter is set to 1. • Bit [26] = The PHY tINIT_COMPLETE value has timed out. This value is specified in the PHY_INI_COM parameter. • Bit [25] = The user-initiated DLL resync has completed. • Bit [24] = A state change has been detected on the dfi_init_complete signal after initialization. • Bit [23] = The assertion of the IN_DRAM_CMD parameter has successfully inhibited the command queue and/or MRR traffic.

Table continues on the next page...

DDRMC_CR80 field descriptions (continued)

Field	Description
	• Bit [22] = The register interface-initiated mode register write has completed and another mode register write may be issued. • Bit [21] = A temperature alert condition (low or high temp) has been detected. • Bit [20] = The last automatic MRR of MR4 indicated a change in the device temperature or refresh rate (TUF bit set). • Bit [19] = The requested mode register read has completed. The chip and data can be read in the PERI_MRR_DA parameter. • Bit [18] = The leveling operation has completed. • Bit [17] = A leveling operation has been requested. • Bit [16] = A DFI update error has occurred. Error information can be found in the UP_ERR_STAT parameter. • Bit [15] = A write leveling error has occurred. Error information can be found in the WRLVL_ERR_STAT parameter. • Bit [14] = A read leveling gate training error has occurred. Error information can be found in the RDLVL_ERROR_STATUS parameter. • Bit [13] = A read leveling error has occurred. Error information can be found in the RDLV_ERR_STAT parameter. • Bit [12] = ODT has been enabled while the MC is programmed for CAS latency 3. This is an unsupported combination. • Bit [11] = The user has programmed an invalid setting associated with user words per burst. Examples: Setting param_reduc when burst length = 2. A 1:2 MC:PHY clock ratio with burst length = 2. • Bit [10] = A wrap cycle crossing a DRAM page has been detected. This is unsupported and may result in memory data corruption. • Bit [9] = The low power operation has been completed. • Bit [8] = The MC initialization has been completed. • Bit [7] = An error occurred on the port command channel. • Bit [6] = Multiple uncorrectable ECC events have been detected. • Bit [5] = An uncorrectable ECC event has been detected. • Bit [4] = Multiple correctable ECC events have been detected. • Bit [3] = A correctable ECC event has been detected. • Bit [2] = Multiple accesses outside the defined PHYSICAL memory space have occurred. • Bit [1] = A memory access outside the defined PHYSICAL memory space has occurred. • Bit [0] = The memory reset is valid on the DFI bus.

34.5.82 Control Register 81 (DDRMC_CR81)

Address: 400A_E000h base + 144h offset = 400A_E144h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR82 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28–0
INT_MASK
	Mask for controller_int signals from the INT_STAT parameter.
	
	Active-high mask bits that control the value of the memory controller_int signal on the ASIC interface.
	• Bit [28] = Masks all interrupt reporting.
	  • 0 = Mask interrupts individually based on the settings of bits [27:0] of this parameter.
	  • 1 = Mask all interrupts. The settings in bits [27:0] of this parameter are not relevant.
	• Bits [27:0] = Individual mask bits for each interrupt in the int_stat parameter. For each bit:
	  • 0 = Do not mask interrupt
	  • 1 = Mask interrupt. This will prevent a set interrupt from causing the controller_int signal to be asserted.

34.5.84 Control Register 83 (DDRMC_CR83)

Address: 400A_E000h base + 14Ch offset = 400A_E14Ch

DDRMC_CR88 field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 TODTL_CMD	DRAM delay requirement from ODT de-assertion to next nonwrite, non-read command. Defines the DRAM timing between an ODT to the next command, in memory clocks • For LPDDR2 memories: This parameter has no meaning for this memory type • For DDR3 memories: Program to the (ODTL_off + 1) value from the memory specification.
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.90 Control Register 89 (DDRMC_CR89)

Address: 400A_E000h base + 164h offset = 400A_E164h

DDRMC_CR89 field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 AODT_WRSMCS	Additional delay to insert between write and read transaction types to the same chip select to meet ODT timing requirements. Any value including 0x0 supported. Defines the number of additional controller clocks of delay to insert after a write command before a read command to the same chip select to meet ODT timing requirements.This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 AODT_RWSMCS	Additional delay to insert between read and write transaction types to the same chip select to meet ODT timing requirements. Defines the number of additional controller clocks of delay to insert after a read command before a write command to the same chip select to meet ODT timing requirements.This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110).

DDRMC_CR91 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 W2R_SMCSDL	Additional delay to insert between writes and reads to the same chip select. Defines the number of additional controller clocks of delay to insert from a write command to a read command to the same chip select. This parameter may be programmed to any value including 0x0.
23–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 R2W_SMCSDL	Additional delay to insert between reads and writes to the same chip select. Program to a non-zero value. Defines the number of additional controller clocks of delay to insert from a read command to a write command to the same chip select. This parameter should be programmed to a non-zero value. The exact value is system-dependent.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 R2R_SMCSDL	Additional delay to insert between two reads to the same chip select. Any value including 0x0 supported. Defines the number of additional controller clocks of delay to insert between two read commands to the same chip select. This parameter may be programmed to any value including 0x0.

DDRMC_CR92 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 TDQSCK_MIN	Additional delay needed for tDQSCK. Defines the minimum value of the timing term tDQSCK, in memory clocks. This holds the delay between the memory clock (read latency cycles after the read command) and the first read DQS rising edge. This parameter is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = 0101).
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 TDQSCK_MAX	Additional delay needed for tDQSCK. Defines the maximum value of the timing term tDQSCK, in memory clocks. This holds the delay between the memory clock (read latency cycles after the read command) and the first read DQS rising edge. This parameter is only applicable when the MC is programmed for the following memory systems:LPDDR2 (dram_class = 0101).
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 W2W_SMCSDL	Additional delay to insert between two writes to the same chip select. Any value including 0x0 supported. Defines the number of additional controller clocks of delay to insert between two write commands to the same chip select. This parameter may be programmed to any value including 0x0.

34.5.94 Control Register 93 (DDRMC_CR93)

Address: 400A_E000h base + 174h offset = 400A_E174h

DDRMC_CR93 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 SWLVL_START	User request to initiate software leveling of type in the SW_LVL_MODE bits. Set to 1 to trigger. Initiates the software leveling operation defined in the SW_LVL_MODE bits. This parameter is write-only and will always read back as 0x0. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 'b0110) 0 No Action 1 Initiate software leveling operation
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SWLVL_LOAD	User request to load delays and execute software leveling. Set to to trigger.

Table continues on the next page...

DDRMC_CR93 field descriptions (continued)

Field	Description
	Triggers the delays to be loaded into the PHY delay lines and initiate a read burst or write strobe for software leveling. This parameter is write-only and will always read back as 0x0. This parameter is only applicable when the MC is programmed for the following memory systems:DDR3 (dram_class = 0110) 0 No action 1 Load delays and start software leveling
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 SW_LVL_MODE	Defines the leveling operation for software leveling. Set to 0 for none, set to 1 for write leveling, set to 2 for read leveling, or set to 3 for gate training. Defines the type of leveling operation performed during the next software leveling operation. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110) 00 No Leveling 01 Write Leveling 10 Read Leveling 11 Gate Training
7–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.95 Control Register 94 (DDRMC_CR94)

Address: 400A_E000h base + 178h offset = 400A_E178h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_CR94 field descriptions

Field	Description
31–24 SWLVL_RESP_0	Leveling response for data slice 0. Response for the software leveling process for data slice 0. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice.This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110).

Table continues on the next page...

DDRMC_CR94 field descriptions (continued)

Field	Description
23–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 LVL_STATUS	Status of write level, read level, and gate training requests. This is used with the LVL_REQ interrupt. Bit (0) correlates to write leveling request, bit (1) correlates to read leveling request, and bit (2) correlates to gate training request. Value of 1indicates request received. Indicates the type of leveling request that resulted in the leveling request interrupt (bit 16) in the int_stat parameter being set to 1. This interrupt will be triggered if any of the PHY request signals are asserted. **NOTE:** For software leveling, the user may ignore this parameter and the lvl_status parameter and trigger a software leveling request through the swlvl_start parameter directly. • Bit [2] = Gate training request status • Bit [1] = Read leveling request status • Bit [0] = Write leveling request status For all bits : • 0 = No request received • Request received through the PHY interface, the internal refresh counters or the register interface. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SWLVL_OP_ DONE	Signals that software leveling is currently in progress. Value of 1 indicates operation complete. Reports on status of the software leveling operation. This parameter will be driven low during initiation, load or exit operations. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110) 0 Operation in process 1 Operation completed
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 SWLVL_EXIT	User request to exit software leveling. Set to 1 to exit. User request to exit software leveling. This parameter is write-only and will always read back as 0x0. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110) 0 No action 1 Exit software leveling

34.5.96 Control Register 95 (DDRMC_CR95)

Address: 400A_E000h base + 17Ch offset = 400A_E17Ch

DDRMC_CR95 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 WRLVL_CS	Specifies the target chip select for the write leveling operation. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110). 0 Targets CS0
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 WRLVL_REQ	User request to initiate write leveling. Set to 1 to trigger. User request to initiate write leveling. This parameter is write-only and will always read back as 0x0. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110). 0 No action 1 Trigger write leveling

Table continues on the next page...

DDRMC_CR95 field descriptions (continued)

Field	Description
15–8 SWLVL_RESP_2	Leveling response for data slice 2. Response for the software leveling process for data slice 2. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)
7–0 SWLVL_RESP_1	Leveling response for data slice 1. Response for the software leveling process for data slice1 . Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)

DDRMC_CR96 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 WRLVL_EN	Enable the MC write leveling module. Set to 1 to enable. Enables the hardware write leveling feature in the memory controller.This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110). 0 Disable. The memory controller will never drive the PHY WRITE LEVEL ENABLE signal. The user may program the write leveling delay manually in the wrlvl_delay_X parameters. 1 Enable. Write leveling will automatically be run at initialization, may be run on demand by setting the PHY WRITE LEVEL ENABLE parameter to 1 to assert the signal, or may be run periodically based on the programming of the wrlvl_refresh_interval parameter.
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR96 field descriptions (continued)

Field	Description
13–8 WLMRD	Delay from issuing MRS to first write leveling strobe. Defines the delay from when an MRS command is issued to when the first write leveling strobe is issued, in controller clocks. This is a write leveling-specific timing specification.This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110).
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 WLDQSEN	Delay from issuing MRS to first DQS strobe for write leveling. Minimum number of controller clocks of delay after memory enters write leveling mode (MRS command issued) before first DQS strobe can be sent. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110).

34.5.98 Control Register 97 (DDRMC_CR97)

Address: 400A_E000h base + 184h offset = 400A_E184h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	WRLVL_REFRESH_INTERVAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR97 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 WRLVL_REG_EN	Enable the PHY WRITE LEVEL DELAY X signals to be programmed when hardware and software leveling are disabled. Set to 1 to enable. Enables direct control of the PHY WRITE LEVEL DELAY X signals through the WRLVL_DL_X parameters. This is used when hardware and software leveling are both disabled.This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110) 0 Disable 1 Enable
23–16 WRLVL_ERR_STAT	Holds the status from the most recent write leveling operation. This parameter is read-only. • Bit [7] = Indicates that the leveling operation exceeded the maximum allowed enable time.This bit will only report errors if the PHY_WRLVL_RESP parameter is programmed to a non-zero value. • Bit [6] = Indicates that the leveling operation exceeded the maximum allowable response time (PHY WRITE LEVEL MAX). This bit will only report errors if the PHY_WRLVL_MAX parameter is programmed to a non-zero value. • Bits [5:0] = Reserved This parameter is used by the write leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)
15–0 WRLVL_REFRESH_INTERVAL	Number of refreshes counted between automatic write leveling commands Sets the maximum number of refreshes allowed between automatic write leveling operations. Clearing this parameter to 0x0 will disable automatic write leveling. If this parameter is programmed to a nonzero value, refresh sequences will be counted and the leveling request interrupt (bit 16) in the int_stat parameter will be set to 1 when the counter expires. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)

34.5.99 Control Register 98 (DDRMC_CR98)

DDRMC_CR102 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR102 field descriptions (continued)

Field	Description
16 RDLVL_GT_ REGEN	Enable the gate delay to be programmed when hardware and software leveling are disabled. Set to 1 to enable.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RDLVL_REG_EN	Enable the delay to be programmed when hardware and software leveling are disabled. Set to 1 to enable.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 RDLVL_BGN_ DLEN	Enables the hardware read leveling logic to begin finding the DQ data eye. If the process is not able to find the beginning of the data window, the delay will be cleared to 0 and the status bit will indicate the inability to locate the start. • 0 = Disable • 1 = Enable This parameter is used by the hardware read leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3(*dram_class* = 0110)

34.5.104 Control Register 103 (DDRMC_CR103)

DDRMC_CR103 field descriptions

Field	Description
31–16 RDLVL_END_ DL0	Indicates the value at which the first DQ transition (0 to 1) was found for data slice X. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice. These parameters are read-only. This parameter is used by the hardware read leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3(*dram_class* = 0110)
15–0 RDLVL_BGN_ DL0	Indicates the value at which the first DQ transition (1 to 0) was found for data slice X. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice. These parameters are read-only. This parameter is used by the hardware read leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3(*dram_class* = 0110)

34.5.105 Control Register 104 (DDRMC_CR104)

DDRMC_CR105 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR105 field descriptions (continued)

Field	Description
15–8 RDLVL_DL_0	Number of delay elements where read DQS is placed within the DQ data eye for data slice 0. This is read-only if the RDLVL_EN parameter is 1. If both the RDLVL_EN and the RDLVL_REG_EN parameters are 0, this can only be programmed during initialization or through software leveling. If the RDLVL_EN parameter is 0 and the RDLVL_REG_EN parameter is 1, this can be programmed at any time. **NOTE:** Value programmed in this field delays the strobe by (period of strobe/128) x the programmed value. For e.g, if the value programmed is 0x20h, the the strobe is delayed by period of strobe/4.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 RDLVL_OFF_ DIR_0	Specifies the direction of the offset for the read level midpoint delay for data slice X. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice. • 0 = Subtract delay • 1 = Add delay This parameter is used by the hardware read leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3(*dram_class* = 0110)

34.5.107 Control Register 106 (DDRMC_CR106)

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 WRR_LATCTL	Controls the weighted round-robin latency option. • 0 = Counters only count when their port has a command waiting to be processed. • 1 = Counters are always running.
23–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 AXI_ASTB_DIS	For certain types of AXI transfers, this parameter may be used to force a standard write transaction instead of a masked write with a read/modify/write sequence. Bit [0] controls AXI port 0, Bit [1] controls AXI port 1, etc. **Note:** When this parameter is set to 1, the AXI strobes will be ignored for the associated port for these types of transfers. This parameter applies to transfers with the following characteristics: • The transaction is aligned to the user word (in the controller core) at the starting and ending address. • The transaction is exactly one user word in length (64 bits). For each port: • 0 = Perform this operation as a masked write with a read/modify/write sequence and use the strobes. • 1 = Perform this operation as a standard write operation (not a read/modify/write) and ignore the strobes.
15–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–0 AXI1_FITYPREG	Clock domain relativity between AXI port 1 and memory controller core. Set to 0 for asynchronous or set to 2 for 1:2 port:core pseudo-sync.

34.5.121 Control Register 120 (DDRMC_CR120)

Address: 400A_E000h base + 1E0h offset = 400A_E1E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_CR120 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 AXI0_PRI1_RPRI	Relative priority of priority 1 commands from port 0.
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 AXI0_PRI0_RPRI	Relative priority of priority 0 commands from port 0.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 WRR_ERR	Shows the weighted round-robin arbitration errors/warnings. This parameter is read-only. • Bit [3] = The port ordering parameter values for paired ports is not sequential. • Bit [2] = The relative priority values for any of the ports paired through the W_RR_WSHR parameter are not identical • Bit [1] = Any of the relative priority parameters have been programmed to a zero value. • Bit [0] = The port ordering parameters do not all contain unique values.

Table continues on the next page...

DDRMC_CR120 field descriptions (continued)

Field	Description
	For each bit: • 0 = No error • 1 = Error
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 W_RR_WSHR	Indicates that the port pair is tied together in arbitration decisions in weighted round-robin arbitration. Bit [0] controls ports 0 and 1, Bit [1] controls port 2 and 3, etc. For each port pair: • 0 = The represented ports are treated independently in arbitration. • 1 = The represented ports are tied together for arbitration.

34.5.122 Control Register 121 (DDRMC_CR121)

Address: 400A_E000h base + 1E4h offset = 400A_E1E4h

DDRMC_CR125 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 PHY_WRLAT	Holds the calculated PHY tPHY_WRLAT timing parameter.
23–16 DLL_RST_ADJ_DLY	Specifies the minimum number of controller clocks after the master delay value is programmed before the DLL reset may be asserted.
15–0 DLL_RST_DELAY	Sets the number of controller clocks that the DLL reset must be held asserted for the DLL. If the DLL RESET signal is being used in the system, this parameter may be useful. If the DLL RESET signal is not being used, this parameter may be ignored.

34.5.127 Control Register 126 (DDRMC_CR126)

Address: 400A_E000h base + 1F8h offset = 400A_E1F8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		PHY_RDLAT						0	UP_ERR_STAT						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR126 field descriptions

Field	Description
31–30 Reserved	This field is reserved.
29–24 PHY_RDDATA_EN	Holds the calculated value of the t_{rddata_en} timing parameter, the number of PHY clocks from the assertion of a read command on the DFI to the assertion of the PHY read data enable signal. This parameter is used to adjust the PHY read data enable signal timing. The minimum supported value for the rdlat_adj parameter is 2, and the minimum supported value for PHY read data enable is 1.
23–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–8 PHY_RDLAT	Holds the t_{phy_rdlat} timing parameter, the maximum number of PHY clocks allowed from the assertion of the PHY read data enable signal to the assertion of the PHY read data valid signal. **NOTE:** The reset value of this bit can change after reset based on internal logic.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–0 UP_ERR_STAT	Reports on errors in the PHY update process. This parameter will be valid when the PHY update error interrupt (bit 15) in the int_stat parameter is set to ’b1. If multiple errors occur, only the last error will be reported in this parameter.

34.5.128 Controla Register 127 (DDRMC_CR127)

Address: 400A_E000h base + 1FCh offset = 400A_E1FCh

DDRMC_CR132 field descriptions

Field	Description
31–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 WRLAT_ADJ	Adjusts the relative timing in memory clocks between PHY write commands and the PHY write data enable signal to conform to PHY timing requirements. **NOTE:** For LPDDR2 memory systems (dram_class = ’b0101), the wrlat_adj value is incremented inside the memory controller by 1 to compensate for the tDSS value from the memory specification.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR132 field descriptions (continued)

Field	Description
5–0 RDLAT_ADJ	Adjusts the relative timing between PHY read commands and the PHY read data enable signal to conform to PHY timing requirements. Setting this parameter to 0x2 will cause the PHY read data enable signal will assert one controller clock after the PHY address signal. Each incremental increase will further delay the PHY read data enable signal. The minimum supported value for this parameter is 2.

34.5.134 Control Register 133 (DDRMC_CR133)

DDRMC_CR138 field descriptions

Field	Description
31–16 PHY_WRLV_ MXDL	Defines the maximum number of delay elements that the hardware write leveling logic will test for the “0” to “1” transition. This parameter is used by the hardware write leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 PHYDRAM_CK_ EN	Holds the PHY t $_{dram\_ck\_en}$ timing parameter, the number of PHY clocks from the de-assertion of the PHY DRAM clock disable signal on the PHY until the first valid rising edge of the clock to the DRAM memories, at the PHY-DRAM boundary. This parameter is used to indicate the number of clocks that the PHY requires to respond to a deassertion of the PHY DRAM clock disable.
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 PHYDRAM_CK_ DIS	Holds the DFI t $_{dram\_ck\_dis}$ timing parameter, the number of PHY clocks from the assertion of the PHY DRAM clock disable signal on the DFI until the clock to the DRAM memories, at the PHY-DRAM boundary, maintains a low value.

34.5.140 Control Register 139 (DDRMC_CR139)

Address: 400A_E000h base + 22Ch offset = 400A_E22Ch

Bit	31–24	23–16	15–8	7–0
R/W	PHY_WRLV_RESPLAT	PHY_WRLV_LOAD	PHY_WRLV_DLL	PHY_WRLV_EN
Reset	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

DDRMC_CR139 field descriptions

Field	Description
31–24 PHY_WRLV_ RESPLAT	Defines the number of PHY clocks after a write level strobe until the response is valid. All PHY timing parameters must be programmed relative to the PHY clock. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)
23–16 PHY_WRLV_ LOAD	Defines the minimum number of PHY clocks required after the write leveling delays are loaded until the first write leveling load may be asserted. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)
15–8 PHY_WRLV_DLL	Defines the number of DFI clocks required for the write leveling delay line to update after a load. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)
7–0 PHY_WRLV_EN	Defines the number of PHY clocks required for the write leveling delay line to update after a load. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)

34.5.141 Control Register 140 (DDRMC_CR140)

Address: 400A_E000h base + 230h offset = 400A_E230h

Bit	31–10	9–0
R	0	PHY_WRLV_WW
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0

DDRMC_CR140 field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–0 PHY_WRLV_ WW	Sets the minimum number of PHY clocks that must occur between write level strobes. This parameter is used by the leveling logic and is only applicable when the MC is programmed for the following memory systems:

DDRMC_CR151 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–16 RDLV_ERR_STA	Reports on errors in the hardware read leveling process. This parameter will be valid when either the read leveling error interrupt or the gate training error interrupt (bits 12 or 13) in the int_stat parameter are set to ’b1. This parameter is read-only.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 RDLV_GAT_DQ_ ZERO_CNT	Defines the number of consecutive “0” responses that the controller must receive in the hardware gate training process to consider a transition from “1” to “0” to be valid. This parameter is used by the hardware gate training logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 RDLVL_DQ_ ZERO_CNT	Defines the number of consecutive “0” responses that the controller must receive in the read leveling process to consider a transition from “1” to “0” to be valid. This parameter is used by the hardware read leveling logic and is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)

DDRMC_CR154 field descriptions

Field	Description
31–27 PAD_ZQ_ EARLY_CMP_ EN_TIMER	This timer defines the time between the enabling of the comparator in the ZQ calibration pad and the beginning of the calibration process with the pad. 0x0 - 0x6 - Reserved 0x7 - 8 cycles .. 0x0D - 14 cycles (recommended setting) .. 0x1E - 31 cycles 0x1F - 32 cycles
26–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–21 PAD_ZQ_MODE	PAD calibration modes 0x0 No pad calibration issued (Default) 0x1 Pad calibration issued whenever memory controller issues a external memory short or Long (ZQCL or ZQCS) commands, including during memory initialization and after self refresh exit (provided controller has been configured for this). 0x2 pad calibration issued whenever memory controller drives only long calibration command to the external memory (ZQCL), including during memory initialization. 0x3 reserved
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–18 DDR_SEL_PAD_ Contr	Programmable Control bits for Other DDR-Pads, like: • DDR_SEL = 11 (DDR3 mode). • DDR_SEL = 10 (LPDDR2 mode).

Table continues on the next page...

DDRMC_CR154 field descriptions (continued)

Field	Description
17–16 DDR_SEL_ZQ_ PAD_Contr	Programmable Control bits for ZQ-Pads, like: • DDR_SEL = 00 (DDR3 mode) • DDR_SEL = 00 (LPDDR2 mode)
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 PAD_ZQ_HW_ FOR	Writing a 1 to this bit will force the hardware pad calibration once. It is the user responsibility to ensure that this bit is asserted at the correct time and when there is no traffic on the DDR interface. The HW PAD calibration staus bit in DDR_CR 156[PAD_ZQ_HW_IN_PROG] is set during the duration of the Pad calibration seq. When the H/W calibration is done, DDR_CR 156[AD_ZQ_HW_IN_PROG] will be cleared by the logic and the pad calibration values in DDR_CR 156[PAD_ZQ_HW_PU_RES] and PAD_ZQ_HW_PD_RES are valid. **NOTE:** It is not required to explicitely clear this bit before the next write. Writing a 0 in this bit has no effect on the PAD calibration logic. Even if this bit is left uncleared after last write, user needs to write a 1 again to this bit to force H/W pad calibration.
13–12 PAD_ZQ_CMP_ OUT_SMP	Defines the amount of cycles between driving the calibration signals to the ZQ calibration pad and sampling the comparator output for result. 00 7 cycles (Default) 01 15 cycles 10 23 cycles 11 31 cycles
11–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.156 Control Register 155 (DDRMC_CR155)

Address: 400A_E000h base + 26Ch offset = 400A_E26Ch

DDRMC_CR155 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 PAD_IBE1	Input buffer enable state for DDR pads corresponding to byte lane 1 (DQ[15:8], DQS[1] and DM[1]). This value takes effect only when PAD_IBE_SEL1 (bit 17) is high, otherwise the buffer enable signal is controlled by the logic.
18 PAD_IBE0	Input buffer enable state for DDR pads corresponding to byte lane 0 (DQ[7:0], DQS[0] and DM[0]). This value takes effect only when PAD_IBE_SEL0 (bit 16) is high, otherwise the buffer enable signal is controlled by the logic.
17 PAD_IBE_SEL1	DDR pad input buffer select override from software for signals corresponding to Byte lane1(DQ[15:8], DQS[1] and DM[1]). If this bit is set then DDR pad IBE is controlled by the state of PAD_IBE1 bit otherwise it is controlled by logic.
16 PAD_IBE_SEL0	DDR pad input buffer select override from software for signals corresponding to Byte lane0(DQ[7:0], DQS[0] and DM[0]).If this bit is set then DDR pad IBE is controlled by the state of PAD_IBE0 bit otherwise it is controlled by logic.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 AXI1_AWCACHE	When this bit is set, it forces the AXI port 1 AWCACHE[0] signal for the DDR controller to be set. If this bit is 0, AXI bus AWCACHE signal works as usual.
10 AXI0_AWCACHE	When this bit is set, it forces the AXI port 0 AWCACHE[0] signal for the DDR controller to be set. If this bit is 0, AXI bus AWCACHE signal works as usual.
9 AXI1_COBUF	Control for AXI1_COBUF signal. AXI port 1 coherent bufferable selection. If the AXI1_AWCACHE bit is set to ’b1 for Bufferable operation, this signal determines exactly what type of bufferable response is returned to the user interface. For guaranteed data coherency across all ports, the user should send all commands with AXI1 Coherent Bufferable signal set to ’b1. 0 Response returned when command and data have been received by the port. 1 Response returned when command accepted into the memory controller core command queue and all associated data has been received by the AXI data port.
8 AXI0_COBUF	Control for AXI0_COBUF signal. AXI port 0 coherent bufferable selection. If the AXI0_AWCACHE bit is set to ’b1 for Bufferable operation, this signal determines exactly what type of bufferable response is returned to the user interface. For guaranteed data coherency across all ports, the user should send all commands with AXI0 Coherent Bufferable signal set to ’b1. 0 Response returned when command and data have been received by the port. 1 Response returned when command accepted into the memory controller command queue and all associated data has been received by the AXI data port.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–3 PAD_ODT_ BYTE1	Termination setting for PADs related to BYTE1 (DQ,DQS and DM) in DDR3 mode only. Not applicable in LPDDR2 mode. 000 termination disabled 001 120 Ohm 010 60 Ohm

Table continues on the next page...

Table continues on the next page...

DDRMC_CR161 field descriptions (continued)

Field	Description
16 ODT_EN	Enables the use of the DRAM ODT pin. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110) 0 The ODT output will not be used. 1 The Controller will assert and deassert the ODT output to DRAM as needed
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 TODTH_RD	Defines the DRAM timing for the minimum ODT high time after an ODT assertion for read data. When these bits are programmed to a value larger than the number of cycles required for a burst, the command-to-command delays must be adjusted to delay commands as needed. For LPDDR2 memories: This parameter has no meaning for this memory type. For DDR3 memories: Program to the tODTH4 or the tODTH8 value from the memory specification, based on the burst length.
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 TODTH_WR	Defines the DRAM timing for the minimum ODT high time after an ODT assertion for write data. When this parameter is programmed to a value larger than the number of cycles required for a burst, the command-to-command delays must be adjusted to delay commands as needed. For LPDDR2 memories: This parameter has no meaning for this memory type. For DDR3 memories: Program to the tODTH4 or the tODTH8 value from the memory specification, based on the burst length.

34.5.163 PHY Register 00 (DDRMC_PHY00)

PHY DQ timing register for data slice 0

Address: 400A_E000h base + 400h offset = 400A_E400h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_PHY00 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_PHY00 field descriptions (continued)

Field	Description
15–12 TSEL_START	Defines the DQ pad dynamic termination select enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 2.
11–8 TSEL_END	Defines the DQ pad dynamic termination select disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 2
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 OE_START	Adjusts the starting point of the DQ pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 1.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 OE_END	Adjusts the ending point of the DQ pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. This field must be set to at least the value of bits [6:4]+2 to prevent disabling the pad before the data is completely written. Recommended setting is 0 x 3.

34.5.164 PHY Register 01 (DDRMC_PHY01)

PHY DQS timing register for data slice 0

Address: 400A_E000h base + 404h offset = 400A_E404h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_PHY01 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 TSEL_START	Defines the DQS pad dynamic termination select enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 2.
11–8 TSEL_END	Defines the DQS pad dynamic termination select disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 6.
7–4 OE_START	Adjusts the starting point of the DQS pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. Recommended setting for this field is 0 x 1.
3–0 OE_END	Adjusts the ending point of the DQS pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution. This field must be set to at least the value of bits [7:4]+2 to prevent disabling the pad before the data is completely written. Recommended setting for this field is 0 x 5.

34.5.165 PHY Register 02 (DDRMC_PHY02)

PHY Gate Control Register for data slice 0.

Address: 400A_E000h base + 408h offset = 400A_E408h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0													Gate_CFG		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_PHY02 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 EN_HALF_CAS	Subtracts 1/2 cycle from the DQS gate value programmed into PHY_GATE_CRn[2:0] by 1/2 cycle. Default 0x0. This is used when the gate is being aligned to the first DQS, and then is removed to move the gate back into the center of the preamble. 0 Do not adjust 1 Adjust the DQS gate by 1/2 clock forward.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SW_HALF_ CYCLE_SHIFT	When PHY_GB_CR[EN_SW_HALF_CYLCLE] is set to ’b1, this setting will override the calculated phase shift detection in the slice between clk and DLL-delayed version of clk_ref for the write DQS (clk_wrdqs). 0 No effect 1 Adds a half clock delay to the write level delay line.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 WRLVL_CLKDL	Adds an extra clock cycle to the delay in the PHY. 0 No change 1 Adds extra clock to the PHY if the delay is at max value, it is not already asserted, and the rising edge has not been located.

Table continues on the next page...

DDRMC_PHY02 field descriptions (continued)

Field	Description
24–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–19 RD_DL_SET	Read delay setting for io_datain FIFO timing. Recommended setting: 0 x 4
18–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 Gate_CFG	Coarse adjust of gate open time. Decreasing this value pulls the gate earlier in time. This field is of use during DQS gate training sequence.

34.5.166 PHY Register 03 (DDRMC_PHY03)

PHY DLL Master Control Register for data slice 0.

Address: 400A_E000h base + 40Ch offset = 400A_E40Ch

DDRMC_PHY10 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DQS_ERROR_ STATUS	Status signal to indicate that the logic gate had to be forced closed. -- ’b0 = Normal operation -- ’b1 = Gate close was forced
23–8 LPBK_DQ_DATA	Reports the actual data or expected data, depending on the setting of the PHY02[RD_DL_SET] parameter bit.
7–4 LPBK_DM_DATA	Reports the actual data mask or the expected data mask, depending on the setting of the phy_gate_lpbk_ctrl_reg_fN_X [20] parameter bit.

Table continues on the next page...

DDRMC_PHY10 field descriptions (continued)

Field	Description
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 LPBK_STATUS	Reports status of loopback errors. * 'b0 = Last Loopback test had no errors. * 'b1 = Last Loopback test contained data errors.
0 LPBK_START	Defines the status of the loopback mode. * 'b0 = Not in loopback mode * 'b1 = In Loopback mode

34.5.169 PHY Register 11 (DDRMC_PHY11)

PHY DLL Status Register 0 for data slice 0.

Address: 400A_E000h base + 42Ch offset = 400A_E42Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_PHY16 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 TSEL_START	Defines the DQ pad dynamic termination select enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 2.

Table continues on the next page...

DDRMC_PHY16 field descriptions (continued)

Field	Description
11–8 TSEL_END	Defines the DQ pad dynamic termination select disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 2
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 OE_START	Adjusts the starting point of the DQ pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 1.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 OE_END	Adjusts the ending point of the DQ pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. This field must be set to at least the value of bits [6:4]+2 to prevent disabling the pad before the data is completely written. Recommended setting is 0 x 3.

34.5.173 PHY Register 17 (DDRMC_PHY17)

Controls PHY slice 1. PHY DQS timing register. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice.

Address: 400A_E000h base + 444h offset = 400A_E444h

Bit	31–16	15–12	11–8	7–4	3–0
R	0	TSEL_START	TSEL_END	OE_START	OE_END
W					
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0

DDRMC_PHY17 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 TSEL_START	Defines the DQS pad dynamic termination select enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 2.
11–8 TSEL_END	Defines the DQS pad dynamic termination select disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution. Recommended setting is 0 x 6.
7–4 OE_START	Adjusts the starting point of the DQS pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. Recommended setting for this field is 0 x 1.
3–0 OE_END	Adjusts the ending point of the DQS pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution. This field must be set to at least the value of bits [7:4]+2 to prevent disabling the pad before the data is completely written. Recommended setting for this field is 0 x 5.

34.5.174 PHY Register 18 (DDRMC_PHY18)

PHY Gate Control Register for data slice 1.

Address: 400A_E000h base + 448h offset = 400A_E448h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0		EN_HALF_CAS	0	SW_HALF_ CYCLE_SHIFT	0	WRLVL_CLKDL	0			RD_DL_SET			0

R	0													Gate_CFG		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_PHY18 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 EN_HALF_CAS	Subtracts 1/2 cycle from the DQS gate value programmed into PHY_GATE_CRn[2:0] by 1/2 cycle. Default 0x0. This is used when the gate is being aligned to the first DQS, and then is removed to move the gate back into the center of the preamble. 0 Do not adjust 1 Adjust the DQS gate by 1/2 clock forward.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SW_HALF_ CYCLE_SHIFT	When PHY_GB_CR[EN_SW_HALF_CYLCLE] is set to ’b1, this setting will override the calculated phase shift detection in the slice between clk and DLL-delayed version of clk_ref for the write DQS (clk_wrdqs). 0 No effect 1 Adds a half clock delay to the write level delay line.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 WRLVL_CLKDL	Adds an extra clock cycle to the delay in the PHY. 0 No change 1 Adds extra clock to the PHY if the delay is at max value, it is not already asserted, and the rising edge has not been located.

Table continues on the next page...

DDRMC_PHY18 field descriptions (continued)

Field	Description
24–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–19 RD_DL_SET	Read delay setting for io_datain FIFO timing. Recommended setting: 0 x 4
18–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 Gate_CFG	Coarse adjust of gate open time. Decreasing this value pulls the gate earlier in time. This field is of use during DQS gate training sequence.

34.5.175 PHY Register 19 (DDRMC_PHY19)

PHY DLL Master Control Register for data slice 1.

Address: 400A_E000h base + 44Ch offset = 400A_E44Ch

Bit	31–8	7–0
R	0	DLL_START_POINT
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

DDRMC_PHY19 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–0 DLL_START_ POINT	This value is loaded into the DLL at initialization and is the value at which the DLL will begin searching for a lock. This field must be set to a value greater than or equal to 4.

34.5.176 PHY Register 20 (DDRMC_PHY20)

PHY DLL Slave Control Register for data slice 1. Data slices are the lowered numbered slices, and the highest number slice (slice 2) is the CA slice

Address: 400A_E000h base + 450h offset = 400A_E450h

Bit	31–15	14–8	7–0
R	0	DLL_WRITE_DL	0
W			
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

DDRMC_PHY20 field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–8 DLL_WRITE_DL	DLL Write delay This is delay setting for the dll line that controls the phase relationship for the write data. **NOTE:** Value programmed in this field delays the strobe by (period of strobe/128)x the programmed value. For e.g, if the value programmed is 0x20h, the the strobe is delayed by period of strobe/4.
7–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.177 PHY Register 26 (DDRMC_PHY26)

PHY Loopback Control Register. Reports status for the PHY for data slice 1.

Address: 400A_E000h base + 468h offset = 400A_E468h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_PHY26 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DQS_ERROR_STATUS	Status signal to indicate that the logic gate had to be forced closed. -- ’b0 = Normal operation -- ’b1 = Gate close was forced
23–8 LPBK_DQ_DATA	Reports the actual data or expected data, depending on the setting of the PHY02[RD_DL_SET] parameter bit.
7–4 LPBK_DM_DATA	Reports the actual data mask or the expected data mask, depending on the setting of the phy_gate_lpbk_ctrl_reg_fN_X [20] parameter bit.

Table continues on the next page...

DDRMC_PHY26 field descriptions (continued)

Field	Description
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 LPBK_STATUS	Reports status of loopback errors. * ’b0 = Last Loopback test had no errors. * ’b1 = Last Loopback test contained data errors.
0 LPBK_START	Defines the status of the loopback mode. * ’b0 = Not in loopback mode * ’b1 = In Loopback mode

34.5.178 PHY Register 27 (DDRMC_PHY27)

PHY DLL Status Register for data slice 1.

Address: 400A_E000h base + 46Ch offset = 400A_E46Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DLL_UNLOCK_VALUE								LOCK							
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_PHY27 field descriptions

Field	Description
31–24 DLL_UNLOCK_ VALUE	Reports the dll_lock_value if the DLL has become unlocked after being locked. This field will be cleared to 0x0 following a system reset. A value of 0x0 indicates that once the dll achieved lock, it has always remained locked.
23–16 LOCK	Holds the last 8 samples of the lock indicator
15–8 DLL_LOCK_ VALUE	Reports the DLL encoder value from the master DLL to the slave DLL’s
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DLL_LOCK	Indicates status of the DLL 0 DLL has not locked 1 DLL is locked

34.5.179 PHY Register 28 (DDRMC_PHY28)

PHY DLL Status Register 2 for data slice 0

Address: 400A_E000h base + 470h offset = 400A_E470h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_PHY43 field descriptions

Field	Description
31–24 DLL_UNLOCK_VALUE	Reports the dll_lock_value if the DLL has become unlocked after being locked. This field will be cleared to 0x0 following a system reset. A value of 0x0 indicates that once the dll achieved lock, it has always remained locked.
23–16 LOCK	Holds the last 8 samples of the lock indicator
15–8 DLL_LOCK_VALUE	Reports the DLL encoder value from the master DLL to the slave DLL's
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DLL_LOCK	Indicates status of the DLL 0 DLL has not locked 1 DLL is locked

34.5.188 PHY Register 44 (DDRMC_PHY44)

PHY DLL Status Register 2 for data slice 0

Address: 400A_E000h base + 4B0h offset = 400A_E4B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								DEC_OUT_WR							
W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_PHY50 field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 PHY logic configured for standard DDR operation 1 PHY gating logic configured for Mobile (LPDDR2) gating operation. The DRAM DQS signals are assumed to be pulled down on the board.
13 DFI_MOBILE_EN	DFI control for Mobile PHYs. 0 PHY gating logic configured for standard DDR 1 PHY gating logic configured for Mobile (LPDDR2) operating logic. The DRAM DQS signals are assumed to be pulled down on the board.
12 DDR3_MODE	Enables the generation of the additional DQS pulse required for DDR3 controllers. 0 No Action 1 Generate Pulse (DDR3 memories)
11 DDR_SEL	Controls the PHY memory system mode. 0 non-LPDDR2 mode 1 LPDDR2 mode
10–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 EN_SW_HALF_CYCLE	Enables the Software Half Cycle Shift 0 Hardware automatically controls any shifting needed for the write level delay line. 1 The setting in PHY_GATE_CR[SW_HALF_CYCLE_SHIFT] bit defines the shift.

Table continues on the next page...

DDRMC_PHY50 field descriptions (continued)

Field	Description
	NOTE: If the user chooses to control the half cycle shift manually, it is important that PHY_GATE_CR[SW_HALF_CYCLE_SHIFT] be cleared to 'b0 if the delay is less than a 1/2 cycle and set to 'b1 if the delay is greater than a 1/2 cycle. It is recommended to allow the hardware to control this automatically.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 CLEAR_FIFO	Clear the gather FIFO. This is an emergency reset for the pointers on the data gather FIFO. 0 No action 1 Clear the FIFO
3–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.192 PHY Register 52 (DDRMC_PHY52)

Address: 400A_E000h base + 4D0h offset = 400A_E4D0h

4 tsel_off_value_ dm	Termination select off value for the data mask
3–1 Reserved	This field is reserved.
0 tsel_rd_value_dm	Termination select read value for the data mask

34.6 Functional Description

This section discusses the programming model and operation of the memory controller.

34.6.1 Address Mapping

The memory controller automatically maps user addresses to the DRAM memory in a contiguous block. Addressing starts at user address 0 and ends at the highest available address according to the size and number of DRAM devices present. This mapping is dependent on how the memory controller is configured.

The mapping of the address space to the internal data storage structure of the DRAM devices is based on the actual size of the DRAM devices available. The size is stored in user-programmable parameters that must be initialized at power up. Certain DRAM devices allow for different mapping options to be chosen, while other DRAM devices depend on the chosen burst length.

34.6.1.1 DDR SDRAM Address Mapping Options

The address structure of DDR SDRAM devices contains the following five fields:

- Chip select
- Row
- Bank
- Column
- Datapath

Each of these fields can be individually addressed when accessing the DRAM.

The maximum widths of the fields are based on the configuration settings. The actual widths of the fields may be smaller if the device address width parameters (DDR_CR73[ROW_DIFF], DDR_CR73[BANK_DIFF], and DDR_CR73[COL_DIFF]) are programmed differently.

34.6.1.2 Maximum Address Space

The maximum user address range is determined by the width of the memory datapath, the number of chip select pins, and the address space of the DRAM device. The maximum amount of memory can be calculated by the following formula:

$$\text{Maximum Memory Size} = \text{Chip Selects} \times 2^{\text{Address}} \times \text{Banks} \times \text{DatapathWidth}$$

See the chip configuration section of the reference manual for the maximum address space calculated for this device.

34.6.1.3 Memory Mapping to Address Space

The *col_diff* and *row_diff* parameters can each range from the maximum configured for the memory controller to seven bits smaller than the maximum configured. This allows the Memory Controller to function with a wide variety of memory sizes. The settings for the *col_diff* and *row_diff* parameters control how the address map is used to decode the

user address to the DRAM chip selects and row and column addresses. The *bank_diff* parameter controls the DRAM bank address information. It is assumed that the values in these parameters never exceed the maximum values configured.

34.6.2 AXI Interface

This Memory Controller contains 2 internal AXI ports which communicate on the AXI bus. Each AXI port uses an AXI interface block to connect to the MC core. An arbitration scheme is required to control the traffic between the buses and the core.

34.6.2.1 Architecture Overview

The Multi-Port Memory Controller was designed for high memory bandwidth utilization and efficient arbitration for high priority requests.

Multi- Port system consists of the following pieces:

- 2 AXI Interfaces
- Arbiter
- Command Queue with Placement Logic
- Write Data Latency Queue
- Read Data Queues
- DRAM Command Processing
- Register Port

34.6.2.2 AXI Interfaces

The core interfaces with 2 AXI data port blocks and 1 register port. The AXI data ports function as AXI slaves to external AXI masters such as CPUs, DMAs, DSPs, and other peripherals. Transfers are burst-based of variable byte counts. The transfer types INCR and WRAP are fully supported. The AXI ports may accept commands from any AXI bus master. The AXI ID signals identify which of the 8192 AXI IDs is associated with the command. This AXI ID is concatenated with an originating port identifier to create a source ID which is used in the core to maintain originator information. The uppermost bit/s of the source ID represent the port number. There are no restrictions on mapping of AXI IDs to AXI bus masters.The AXI interfaces handle all communication between the AXI and the core. Each interface contains five separate channels of traffic to/from the AXI bus: write response, read command, write command, read data and write data. Each port will always support full-size transfers where the full data port width is utilized on each beat. In addition, each port can be independently programmed to support narrow transfers, where not all the bits of the data port width are used. This translates to a bytes-per-beat size that is less than the port data width. For a multiport configuration where the port data widths are not uniform, the transfer size that defines a narrow transfer will vary based on each port's data width. There are no fixed timing requirements on a port between the traffic channels when the narrow transfer option is disabled, and in this case, write data may arrive before, with, or after the write command. When the narrow transfer option is enabled, a port will not accept write data until it has received the command and is aware of the total byte count associated with that command.

34.6.2.3 Restrictions on the AXI Bus

For this Memory Controller, the following restrictions exist:

- FIXED burst types are not supported.
- The response signals will never respond with a DECERR response type.
- Cacheable, read allocate or write allocate commands are not supported.
- WRAP commands must be aligned.
- Write data can not be interleaved. Write data must be presented to the memory controller in the same order as the write commands.
- Each port may only issue a fixed number of narrow transfers at a time. The implementation requires that each requestor must be individually enabled for narrow transfers, and that all commands from these requestors be counted in this limit, whether they are narrow transfers or not.

- Each ports may only monitor the exclusivity of a limited number of transactions at any time. In addition, each port will only maintain one exclusive monitor per requestor at a time.
- Locked access is not configured for this memory controller

34.6.2.4 Internal Command Handling

The Memory Controller uses placement logic to fill the command queue with a command order that maximizes the throughput and efficiency of the core. Re-ordering of commands depends on the restrictions of the AXI bus. If the placement logic is being used, the Memory Controller will optimize the core by re-ordering read and write commands as necessary. Read and write commands from individual ports are not affected by other ports. The following re-ordering rules apply to any one port on this memory controller:

- Two read commands from the same AXI ID on a port will not be re-ordered and will always execute in the same order as they were accepted into their port.
- Two read commands from different AXI IDs on a port may be automatically re-ordered in the core to execute out-of-order.
  - When commands from different AXI IDs are re-ordered, read data returned to the AXI port interfaces will also be out-of-order and may be interleaved. To avoid re-ordering within a port, the AXI bus master should use one AXI ID for all commands from any port.
- Two write commands from the same AXI ID on a port must remain sequential and will not be reordered. These transactions will always occur in the order that the commands were received at the port.
- Two write commands from different AXI IDs on a port must remain sequential and will not be re-ordered. These transactions will always occur in the order that the commands were received at the port.
- A read command that follows a write command from the same AXI ID may be re-ordered to execute in an optimal order, as long as there are no collisions between the commands.
- A read command that follows a write command from a different AXI ID on a port may be reordered to execute in an optimal order, as long as there are no collisions between the commands.

- A write command that follows a read command from the same AXI ID may be re-ordered to execute in an optimal order, as long as there are no collisions between the commands.
- A write command that follows a read command from a different AXI ID on a port may be reordered to execute in an optimal order, as long as there are no collisions between the commands.

Command handling is summarized in the following table.

Table 34-199. Re-Ordering / Interleaving Behavior

Commands	AXI IDs	Can Commands be Re-Arranged and Data be Interleaved?
Two Read Commands from 1 port	Same	No
Two Read Commands from 1 port	Different	Yes
Two Read Commands from Different Ports	Same or Different	Yes
Two Write Commands from 1 port	Same	No
Two Write Commands from 1 port	Different	No
Two Write Commands from Different Ports	Same or Different	Yes
Read following a Write from 1 port	Same	Yes
Read following a Write from 1 port	Different	Yes
Read following a Write from different ports	Same or Different	Yes
Write following a Read from 1 port	Same	Yes
Write following a Read from 1 port	Different	Yes
Write following a Read from different ports	Same or Different	Yes

An incoming AXI transaction is mapped into a core-level transaction, then synchronized from the AXI clock domain to the core clock domain and stored in the AXI port FIFOs. Each instruction consists of an address, size, length and AXI ID. Since a port may utilize multiple AXI IDs, the source ID that is used in the core is a combination of both the port and identifier information. This concatenation occurs in the Arbiter and this source ID is used in the placement logic. From the AXI FIFOs, the transaction is presented to the Arbiter which arbitrates requests from all ports and forwards a single transaction to the core.

34.6.2.5 Controller configuration

- **Datapath Width** - Each port has a data interface width of 64 bits.
- **Width of the ID** - Each port is configured with a AXI ID of 13 bits.

- **Priority Definition** - Command priority is defined based on the port and the command type. For each port Y, there is an AXIY_R_PRI bit which defines priorities for all read commands and an AXIY_W_PRI bit which defines priorities for all write commands. Supported priority values range from 0 to 3, with 0 as the highest priority.
- 32 bit wide asynchronous register interface
- **Buffering** - Each data port contains a command, a read and a write FIFO, and a response storage array. In addition, each programmable port contains an asynchronous response FIFO to synchronize the memory response to the port time domain when operating asynchronously.
- **Narrow Transfer FIFO** - Since any command could be a full-size or narrow transwer, an entry is created in the port narrow transfer FIFO with the address, bytes-per-beat and a narrow transfer flag for each command. Each port has been configured with a set number of entries in this FIFO. Therefore, if a port receives enough commands to fill the narrow transfer FIFO, the associated port command FIFO may be stalled from accepting more commands. Therefore, the user should set the depths of the narrow transfer FIFOs accordingly.
- **Exclusive Access Buffer Depth** - This feature allows individual sources to monitor activity on memory locations. This type of access will only be used if exclusive access commands are issued to the memory controller by driving the AXI port Y atomic access indicator to 'b01 with a read command. Each port of this Memory Controller contains 1 exclusive buffer and therefore each port may monitor the exclusivity of up to 1 transaction at any time. Refer to Exclusive Access Option for more information.
- **Error Detection** When an illegal operational condition is detected on a new AXI transaction entering the port, the port responds through an AXI error signal, by asserting the interrupt signal from the memory controller, and recording the error signature in the register space.

  The AXI error signal flagged is dependent on the type of transaction that caused the error (read or write). If the error was associated with the command, the port command error interrupt (bit 7) will be set in the DDR_CR80[INT_STAT], and the address, source ID and type related to the error will be saved in the DDR_CR85[P_CMDERRADD], DDR_CR86[P_CMDERRID] and DDR_CR86[P_CMDERRTYP] bits.

34.6.2.6 Port Clocking

There are two user-selectable modes of operation for each of the AXI port interfaces. The mode is set by programming the corresponding *axiY_fitypreg* parameter (where Y represents the port number). The two settings are:

- **Asynchronous ('b00)**

  The AXI interface port and the core operate on clocks that are mismatched in frequency and phase. The AXI interface port FIFOs use two stages of synchronization logic to synchronize commands, write data and read data to the appropriate clock domain.

- **1:2 Port: Core Pseudo-Synchronous ('b10)**

  The AXI interface port operates at half of the frequency of the core frequency, with clocks that are aligned in phase. One stage of the two-stage synchronization logic of the FIFOs will be utilized to synchronize commands, write data and read data to the appropriate clock domain.

34.6.2.7 AXI Port FIFOs

Incoming transactions from the AXI interfaces are processed by the interface logic and mapped into equivalent transactions on the core bus. These transactions are queued into each port's command FIFO.

34.6.2.8 Command FIFO

Prior to entering the port command FIFO, the AXI port interface blocks convert the AXI transactions into core transactions.

34.6.2.8.1 In-Port Arbitration

Within each port, it is possible that both the read and write command channel of the AXI bus are active concurrently. If this occurs, each port performs a simple arbitration to select the command to pass through to the Arbiter. This arbitration is based on the following factors, in order of importance:

1. Priority of read commands versus priority of write commands for this port (values in the bits *axiY_r_pri* versus *axiY_w_pri* (where Y represents the port number)).

2. Default Read over Write preference. If both read and write commands are accepted simultaneously, and their priorities match, then the read channel will be selected first.

The following table shows the system behavior when the port FIFO is full, allowing commands to accumulate on both channels. The commands will be arbitrated into the port command FIFO based on the order that they are accepted at the port.

Table 34-200. Port Arbitration Example 1

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
1	FULL	1st Read	Any			None (FIFO full)
2	FULL			1st Write	Any	None (FIFO full)
3	Available					1st Read (Arrived First)
4	Available	2nd Read	Any			1st Write (Arrived First)
5	Available					2nd Read

The following table shows the system behavior when read and write commands are accepted simultaneously. The commands will be arbitrated into the port command FIFO based on priority for that type of command. When the commands are not simultaneous, they will be arbitrated based on the order that they are accepted at the port.

Table 34-201. Port Arbitration Example 2

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
1	Available	1st Read	Lower	1st Write	Higher	1st Write (Higher Priority)
2	Available			2nd Write	Higher	1st Read (Arrived First)
3	Available					2nd Write
4	Available	2nd Read	Lower	3rd Write	Higher	3rd Write (Higher Priority)
5	Available					2nd Read

The following table shows the system behavior when read and write commands are accepted simultaneously and their port priorities are the same. Read commands will automatically be arbitrated ahead of write commands when both other conditions match. When the commands are not simultaneous, they will be arbitrated based on the order that they are accepted at the port.

Table 34-202. Port Arbitration Example 3

Cycle	Port Command FIFO	Read Channel		Write Channel		Arbitrated into Port
		Command Accepted	Priority	Command Accepted	Priority	
1	Available	1st Read	Same	1st Write	Same	1st Read (Read over Write Priority)
2	Available	2nd Read	Same			1st Write (Arrived First)
3	Available			2nd Write	Same	2nd Read (Arrived First)
4	Available					2nd Write
5	Available	3rd Read	Same	3rd Write	Same	3rd Read (Read over Write Priority)
6	Available					3rd Write

34.6.2.9 Read FIFO

There is only one streaming read data interface out from the core for all AXI ports, regardless of the number of ports or the number of AXI IDs for any port. The Memory Controller maps this data stream back to the proper port. The AXI bus master must map the data back to the originator associated with each AXI ID.

With this singular data interface, the AXI port must be ready to accept the read data as soon as it is available on the internal core bus to avoid stalling the memory controller. The AXI port Y read data valid indicator output signal will be asserted whenever the port has received valid data from memory that can be passed back to the originator associated with that AXI ID.

If the core stalls while waiting for the read data in the read data queue to be off-loaded, the performance across all the ports in the system will be affected.

34.6.2.10 Write FIFO

The depth of the write FIFO depends on the typical byte count of a burst write transaction. Note that there is a write data queue inside the core as well. Therefore, the purpose of the write FIFO is to allow the AXI bus to off load its write data completely before the data is transferred to the core buffers. Each port has a distinct write channel into the core write data queue. If there are multiple AXI IDs for a port, they will all share the channel for that port.

While an AXI write may begin at any address, aligned or un-aligned, the protocol specifies that it must complete at an address that is aligned to the beat size.

Depending on the type of transfer, the write data may arrive before the command. However, if the originator associated with the AXI ID sending the data is capable of sending narrow transfers, then the write data will not be accepted until the command has been received.

34.6.2.11 Response Interface

When a write request is accepted into the AXI interface, an entry will be created in the Response Storage Array for that command. The array will maintain information on the order of received commands from each AXI ID for each port. Write responses will be returned in the same order as the commands were received, regardless of the AXI ID or the type of response requested (bufferable, coherent bufferable or non-bufferable). When a write response is ready, the array will verify that this is oldest command for that port and if so, the response will be sent out. The timing of this response is dependent on the type of response requested and the contents of the command queue. Responses for bufferable commands will be available when the port has received all of the data, responses for coherent bufferable commands will be available when the core has received the command and the port has received all the data and responses for non-bufferable commands will be available when all data has been sent to the DFI. It is possible that the response for a newer command for that port will be ready and waiting until the responses for all older commands for that port are ready and sent to the user interface. Write responses will be returned to the AXI master through the signal AXI port Y write response signal and its associated valid indicator, the AXI port Y read data valid indicator signal.

34.6.2.12 Bufferable, Coherent Bufferable and Non-Bufferable Response Types

DDR_CR155[AXI0_COBUF] bit controls the timing of the response being sent by the controller for a bufferable write command

When AXI0_COBUF bit is set to '0', a bufferable write command is issued, then the response for that write command is sent on the crossbar interface when the command and data reception is completed on the AXI0 port. There is no guarantee of data coherency across all AXI ports. If data coherency is NOT required across ports, this setting will provide the fastest response time for bufferable write requests.

When DDR_CR155[AXI1_COBUF] set to '1', a coherent bufferable write command is issued, then the response for that write command is sent on the crossbar interface when the command queue and data reception is completed on theAXI1 port. This guarantees data coherency across all ports but reduces the overall write response latency relative to the non-bufferable option.

34.6.2.13 Exclusive Access Option

The exclusive access feature allows a master to monitor if a memory area has been altered since its last read. Exclusive access does not imply that the memory area is locked; other AXI IDs of that port, or other ports, may access the area for reads or writes even though an exclusive access exists. If any writes occur to a memory area with a valid exclusive access request, the master will lose exclusivity and be informed of this status when it attempts to write to the area again. A loss of exclusivity does not trigger an interrupt or any error conditions; however, the AXI protocol requires that the write data is not written to memory if an exclusive write fails its exclusivity check. The master that has lost exclusivity must determine whether to restart the sequence by requesting another exclusive read or to write the data to the memory regardless via a non-exclusive write.

34.6.2.14 Error Responses

Refer to register description section for error responses and handling.

34.6.2.15 DRAM Command Processing

The DRAM command processing logic is used to process the commands in the command queue. The logic organizes the commands to the memories in such a way that data throughput is maximized. Bank opening and closing cycles are used for data transfers.

34.6.3 Multi-Port Arbiter

The Arbiter is responsible for arbitrating requests from the ports and sending requests to the MC core. Each transaction received at the Arbiter logic has an associated priority, which works with each port's arbitration logic to determine how ports issue requests to the MC core. This Memory Controller supports the Weighted Round-Robin arbitration scheme. The Arbiter logic routes read data from the MC core to the appropriate port. The requesting port is assumed able to receive the data. Write data from each port is connected directly to its own write data interface in the MC core, allowing the ports to independently pass write data to the MC core buffers.

34.6.3.1 Arbitration Overview

The weighted round-robin arbitration scheme is a three-step arbitration system. All commands are routed into priority groups based on the priority of the requests. Then, within each priority group, requests are serviced according to the "weight" (relative priority) of each port. Finally, each priority group presents a single command to the priority select module, which passes the highest priority command on to the MC core. This arbitration scheme also supports two additional features. For situations where the priority and the relative priority for multiple commands are identical, a port ordering system in included whereby the user may adjust the order in which the ports are considered. Secondly, for situations where two ports may be related, a mechanism is included which allows a pair of ports to share arbitration bandwidth for bandwidth efficiency. Weighted round-robin arbitration is a complex arbitration scheme. To understand the operation, each concept must be first understood individually. Understanding Round-Robin Operation through Understanding Port Ordering describe the various components of weighted round-robin arbitration. Note that the examples may utilize a greater number of ports and a larger number of priority levels than are available in this Memory Controller. This is done intentionally for explanation.

34.6.3.2 Understanding Round-Robin Operation

Round-robin operation is the simplest form of arbitration and is ideal for systems that do not require requests to be treated preferentially to maintain bandwidth or minimize latency. This scheme uses a counter that rotates through the port numbers, incrementing every time a port request is granted. If the port that the counter is referencing has an active request, and the MC core command queue is not full, then this request will be sent to the MC core. If there is not an active request for that port, then the port will be skipped

and the next port will be checked. The counter will increment by one whenever any request has been processed, regardless of which port's request was arbitrated. Round-robin arbitration ensures that each port's requests can be successfully arbitrated into the MC core every N cycles, where N is the number of ports in the Memory Controller. No port will ever be locked out, and any port can have its requests serviced on every cycle as long as all other ports are quiet and the command queue is not full. An example of the round-robin scheme is shown in the following table. Cycles 0, 2 and 6 show the system behavior when the command queue is full. Cycle 8 and 11 show the system behavior when the port addressed by the arbitration counter does not have an active request. In particular, note cycle 11: The port addressed by the arbitration counter (0) is not requesting, so the counter scans through the other ports, in incrementing order, to find an active request. Port 2 is requesting and therefore wins arbitration, but the counter only increments to port 1 which was the next port in the sequence. All other cycles show normal behavior.

Table 34-203. Round-Robin Operation Example

Cycle	Port Addressed by the Arbitration Counter	Ports Requesting				Command Queue Full?	Arbitration Winner	Value of Counter at Next Cycle
		P0	P1	P2	P3			
0	0	Y	Y	Y	Y	Yes	None	0
1	0	Y	Y	Y	Y	No	P0	1
2	1		Y	Y	Y	Yes	None	1
3	1	Y	Y	Y	Y	No	P1	2
4	2	Y		Y	Y	No	P2	3
5	3	Y			Y	No	P3	0
6	0	Y		Y		Yes	None	0
7	0	Y		Y		No	P0	1
8	1			Y		No	P2	2
9	2			Y	Y	No	P2	3
10	3	Y			Y	No	P3	0
11	0			Y		No	P2	1

34.6.3.3 Understanding Port Priority

For AXI ports, the priority is associated with a port and each port has separate priority parameter for reads and writes. These values are stored into the programmable bits *axiY_r_pri* and *axiY_w_pri* (where Y represents the port number) at controller initialization. Internally, the ports are organized into priority groups based on their priority setting. The priority value is also used by the placement logic inside the MC core when filling the command queue. A priority value of 0 is highest priority, and a priority

value of (decimal) 3 is the lowest priority in the Memory Controller. The user may program at priority level 0; however, it is best to reserve this priority value so that the placement queue can elevate to this level through aging.

34.6.3.4 Understanding Relative Priority

Inside each priority group, the relative priority is used to determine arbitration. The Memory Controller contains 4 identical priority groups with logic that selects between the requests from all commands at that priority level. The relative priority parameters *axiY_priZ_rpri* (where Y is the port number and Z is the priority group) "weight" the ports for each level and determine how the priority group will be arbitrated. The following figure shows this type of arbitration system.

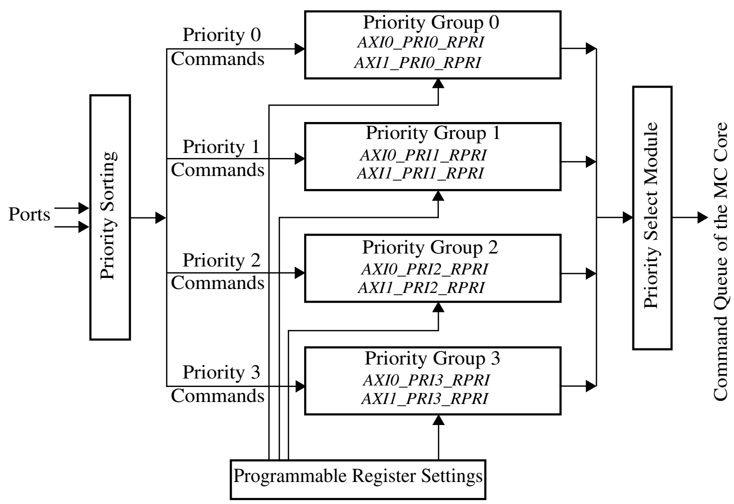

Figure 34-194. Weighted Round-Robin Priority Group Structure

By using the relative priority concept, the arbitration is skewed in favor of certain ports based on user programming. Note that the relative priority bits have a minimum acceptable value of 1 to prevent port lockout. A '0' value will cause an error condition.

If the relative priorities are all programmed to the same value within any priority group, then the arbitration will mimic a version of simple round-robin scheme within that priority group. Instead of incrementing whenever any request is processed, the simple round-robin counter will only increment to the next port after the value in the *axiY_priZ_rpri* bits number of requests are processed.

Each port Y for priority level Z will be allocated the ratio of that port's relative priority bits (*axiY_priZ_rpri*) to the sum of all requesting port's relative priority values. If a particular port is not requesting, then it is not included in the sum calculation, which means that the arbitration will be split with relative proportions among the requesting ports.

As an example, consider a system with 4 ports where all requests are at priority 0. This system is described in the following table.

Table 34-204. Relative Priority Example

Memory Controller bits	System A
AXI0_PRI0_RPRI	1
AXI1_PRI0_RPRI	2
AXI2_PRI0_RPRI	3
AXI3_PRI0_RPRI	4

For this system, port 0 will be serviced 1/(1+2+3+4) = 1/10 of the time and Port 3 will be serviced 4/ (1+2+3+4) = 4/10 of the time. However, if Port 2 is not actively requesting, then port 0 will be serviced 1/(1+2+4) = 1/7 of the time and port 3 will be serviced 4/ (1+2+4) = 4/7 of the time.

In order to ensure that relative priorities are maintained, there is a weight counter for each port within each priority group. These counters track the number of transactions accepted for that port in that priority group. When any counter value reaches the programmed relative port priority, the scan order for that priority group will be internally modified. The port that has met its relative priority will be dynamically positioned to the bottom of the scan order (and its counter will be reset), allowing other ports a preferential position.

For ports that are not expected to issue requests at a certain priority level, the associated relative priority parameter should be programmed to 0x1. This allows for minimum allocation without the risk of lock out in case a command appears.

34.6.3.5 Understanding Port Ordering

With simple round-robin arbitration, the ports are scanned based on their port number in incrementing order in the system. Assuming that the command queue is not full, the port referenced by the counter is examined for valid incoming transactions. If there is an active request, it will be accepted. Otherwise, the next port in the scan order will be checked, and its request accepted. For the Memory Controller with weighted round-robin arbitration, the user has the option of adjusting the order that the ports are scanned. This is useful if requests from certain ports are more critical, or if a specific order may reduce contention between ports. The *axiY_p_odr* bits are used to set this new scan order. A value of 'b0 gives the highest listing in the scan order, and a value of 'b1 is the lowest listing in the scan order. If the 2 *axiY_p_odr* bits are programmed with unique values, then the scan order will be modified to proceed sequentially in this new order. If any of the port ordering parameters have the same value, then those ports will still be equal in the arbitration test. In this case, the port number will select between these ports, with the lower-numbered port automatically being selected first. To demonstrate this concept,

consider a system with 8 ports and the two port orders as shown in the following table. For System B, the port ordering bits all contain unique values, so the resulting order is entirely based on the values of the parameters. For System C, three ports have the same programmed values for the port order. For these three ports, the port number sets the order. Remaining ports follow the port ordering parameters. If all of the port ordering bits are programmed with the same value, then the scan order will default to the numbered port order.

Table 34-205. Port Ordering Example

Memory Controller Parameter	System B	System C
axi0_p_odr	3	3
axi1_p_odr	4	0
axi2_p_odr	5	5
axi3_p_odr	6	6
axi4_p_odr	7	7
axi5_p_odr	0	1
axi6_p_odr	2	0
axi7_p_odr	1	0
Port Scan Order	P5-P7-P6-P0-P1-P2-P3-P4	P1-P6-P7-P5-P0-P2-P3-P4

34.6.3.6 Weighted Round-Robin Arbitration Summary

The MC weighted round-robin arbitration system combines the concepts of round-robin operation, priority, relative priority and port ordering. The incoming commands are separated into priority groups based on the priority of the associated port for that type of command. Within each priority group, the relative priority values are examined to determine the arbitration winner. If the relative priority values are identical and no individual command can be selected, then the scan order is used to select between the requests. In the end, the highest priority command, from the highest relative priority port, with the highest location in the scan order will be selected and sent to the MC core. As an example, consider the system described in Table 34-206. The counters refer to the counters that exist for each port within each priority group to ensure that relative priorities are maintained. For simplification, the command queue is considered to never be full and commands are only received at priority level 0. The behavior is shown in Table 34-207. The highest port in the scan order that is requesting always wins arbitration, and the scan order is dynamically modified when any port counter reaches its allocated relative priority value. Note that if the command queue was considered, then cycles where the command queue was full would not have any arbitration winner and therefore, the counter values and scan order would not change on that cycle.

Table 34-206. System D Specification

Memory Controller Parameter	Port 0	Port 1	Port 2	Port 3
AXIY_PRI0_RPRI	4	3	2	1
AXIY_P_ODR	0	1	2	3

Table 34-207. System D Operation

Cycle	Ports Requesting				Arbitration Winner	Next Counter				Next Scan Order
	P0	P1	P2	P3		P0	P1	P2	P3	
										P0-P1-P2-P3
0	Y			Y	P0	1	0	0	0	P0-P1-P2-P3
1	Y		Y	Y	P0	2	0	0	0	P0-P1-P2-P3
2	Y	Y	Y	Y	P0	3	0	0	0	P0-P1-P2-P3
3	Y	Y	Y	Y	P0	4	0	0	0	P1-P2-P3-P0
4	Y	Y	Y	Y	P1	0	1	0	0	P1-P2-P3-P0
5	Y	Y	Y	Y	P1	0	2	0	0	P1-P2-P3-P0
6	Y	Y	Y	Y	P1	0	3	0	0	P2-P3-P0-P1
7	Y		Y	Y	P2	0	0	1	0	P2-P3-P0-P1
8	Y		Y	Y	P2	0	0	2	0	P3-P0-P1-P2
9	Y			Y	P3	0	0	0	1	P0-P1-P2-P3
10	Y		Y	Y	P0	1	0	0	0	P0-P1-P2-P3
11			Y	Y	P2	1	0	1	0	P0-P1-P2-P3
12			Y	Y	P2	1	0	2	0	P0-P1-P3-P2

If the same system also contains two ports that only request at priority level 1, then the system behavior will be slightly altered. The addition of these 2 ports creates the second priority group structure that adds to the arbitration complexity. Table 34-208 describes this system. The blue text highlights the priority level change for P4 and P5. Again, for simplification, the command queue is considered to never be full and it is assumed that commands from ports 0, 1, 2 and 3 are only received at priority level 0. The behavior is shown in Table 34-209. Note that if any of the priority 0 ports (P0, P1, P2, P3) are requesting, the system behavior will match the behavior when there is only one priority group, as in Table 34-207. Ports 4 and 5 can only win arbitration when no higher-priority commands exist.

Table 34-208. System E Specification

Memory Controller bits	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5
AXIY_PRI0_RPRI	4	3	2	1	1	1
AXIY_PRI1_RPRI	1	1	1	1	3	2
AXIY_P_ODR	0	1	2	3	4	5

Table 34-209. System E Operation

Cycle	Ports Requesting						Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5		P0	P1	P2	P3	P4	P5	
														Priority 0: P0-P1-P2-P3 Priority 1: P4-P5
0			Y			Y	P2	0	0	1	0	0	0	P0-P1-P2-P3 P4-P5
1	Y		Y			Y	P0	1	0	1	0	0	0	P0-P1-P2-P3 P4-P5
2			Y			Y	P2	1	0	2	0	0	0	P0-P1-P3-P2 P4-P5
3	Y		Y		Y	Y	P0	2	0	0	0	0	0	P0-P1-P3-P2 P4-P5
4			Y		Y	Y	P2	2	0	1	0	0	0	P0-P1-P3-P2 P4-P5
5					Y	Y	P4	2	0	1	0	1	0	P0-P1-P3-P2 P4-P5
6		Y			Y	Y	P1	2	1	1	0	1	0	P0-P1-P3-P2 P4-P5
7					Y	Y	P4	2	1	1	0	2	0	P0-P1-P3-P2 P4-P5
8					Y	Y	P4	2	1	1	0	3	0	P0-P1-P3-P2 P5-P4
9					Y	Y	P5	2	1	1	0	0	1	P0-P1-P3-P2 P5-P4
10					Y		P4	2	0	1	0	1	1	P0-P1-P3-P2 P5-P4

34.6.3.7 Priority Relaxing

From Table 34-209, it is evident that ports at lower priority levels will not win arbitration in weighted round-robin arbitration unless there are no higher priority requests. This could mean that, in a situation where high priority requests are being received continuously, lower priority requests could be locked out indefinitely. To avoid this scenario and control the arbitration latency for lower-priority commands, it is possible to

disable priority groups temporarily. This is known as priority relaxing, and it is a time-controlled function. Each higher priority group will be temporarily disabled when the pre-set counter value for the lower priority group has been reached and a request is waiting. The *axiY_prirlx* bits set the counter value for port Y at which the priority relax condition will be triggered. The timing counters inside each port are controlled by the DDR_CR119[WRR_LATCTL]. When the latency control bit is set to 'b1, the timing counters are free-running. Any timing counter may hit its *axiY_prirlx* bits value at any point. When this occurs, higher-priority groups are disabled to allow a waiting request for this port to be processed. This results in a random latency for each port, but the maximum latency is fixed at the *axiY_prirlx* bits value. If the current port does not have any commands waiting when the timing counter hits the relax value, then the counter will be reset and the Arbiter will function normally. When the WRR_LATCTL bit is cleared to 'b0, the timing counters only count while that port has a waiting request that is not being processed. In this case, when the port's *axiY_prirlx* bits value is reached, all priority groups at priority levels higher than the waiting request are disabled. This port's command is granted arbitration and is moved through to the MC core. Since the priority relax parameters and counters are associated with individual ports, it is possible that multiple priority relax counters could reach their specified value simultaneously. In this case, the lower priority command will be arbitrated first and then the higher priority command. This situation could alter the arbitration latency slightly, causing it to be longer than the expected value in the priority relax parameter. Consider the System F as described in Table 34-210. The same conditions apply as for the previous example. The command queue is considered to never be full, commands from ports 0, 1, 2 and 3 are only received at priority level 0, and commands from ports 4 and 5 are only received at priority 1.

Table 34-210. System F Specification

Memory Controller bits	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5
AXIY_PRI0_RPRI	4	3	2	1	1	1
AXIY_PRI1_RPRI	1	1	1	1	2	1
AXIY_P_ODR	0	1	2	3	4	5

Table 34-211 shows the system behavior. The exact settings of the latency control and priority relax parameters are not shown. Instead, the "Relaxed Ports" column indicates which, if any, ports have hit their priority relax values. The following cycles are important to observe:

- Cycles 1 and 7: A port relaxes while a higher priority request and a higher scan order request are both present. The relaxed port still wins arbitration.

- Cycle 4: Two ports of the same priority relax. The higher scan order request wins arbitration.
- Cycle 5: Two ports of different priorities relax.

The lower priority port that relaxed wins arbitration. The higher priority port that relaxed will maintain its relax condition, and win arbitration in the next cycle.

Table 34-211. System F Operation with Priority Relaxing

Cycle	Ports Requesting						Relaxed Ports	Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5			P0	P1	P2	P3	P4	P5	
															Priority 0: P0-P1-P2-P3 Priority 1: P5-P4
0			Y		Y	Y		P2	0	0	1	0	0	0	P0-P1-P2-P3 P5-P4
1			Y		Y	Y	P5	P5	0	0	1	0	0	1	P0-P1-P2-P3 P4-P5
2			Y		Y	Y		P2	0	0	2	0	0	0	P0-P1-P3-P2 P4-P5
3		Y			Y	Y		P1	0	1	0	0	0	0	P0-P1-P3-P2 P4-P5
4	Y				Y	Y	P4,P5	P4	0	1	0	0	1	0	P0-P1-P3-P2 P4-P5
5	Y				Y	Y	P0,P5	P5	0	1	0	0	1	1	P0-P1-P3-P2 P4-P5
6	Y				Y		P0	P0	1	1	0	0	1	0	P0-P1-P3-P2 P4-P5
7	Y				Y	Y	P4	P4	1	1	0	0	2	0	P0-P1-P3-P2 P5-P4
8	Y	Y	Y			Y		P0	2	1	0	0	0	0	P0-P1-P3-P2 P5-P4

Table continues on the next page...

Table 34-211. System F Operation with Priority Relaxing (continued)

Cycle	Ports Requesting						Relaxed Ports	Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5			P0	P1	P2	P3	P4	P5	
9		Y	Y	Y		Y		P1	2	2	0	0	0	0	P0-P1-P3-P2 P5-P4
10		Y	Y	Y		Y	P2	P2	2	2	1	0	0	0	P0-P1-P3-P2 P5-P4

Priority relaxing allows low priority commands to be able to move through the Arbiter to the MC core. This will ensure that the system can meet maximum latency requirements.

34.6.3.8 Port Pairing

The Memory Controller Arbiter incorporates a feature which allows adjacent ports to be grouped together and considered jointly for arbitration. The DDR_CR120[W_RR_WSHR] controls this function, with 1 bit per pair of ports in the Memory Controller. Bit 0 controls ports 0 and 1, Bit 1 controls ports 2 and 3, etc. If the Memory Controller interfaces to an odd number of ports, the highest numbered port is excluded from the port pairing system. Since the ports are grouped together, their relative priorities are not considered separately. Referring to Understanding Relative Priority, the general formula for port priority allocation is the ratio of that port's relative priority bits (AXIY_PRIYZ_RELPRI) to the sum of all requesting port's relative priority values. In this case, the relative priority value of only one of the paired ports is used for the sum calculation. This means that the bandwidth will be divided differently among the ports. If the port pair is at the top of the scan order, and either of the ports is requesting, then the requesting port will win arbitration. If both are requesting, port ordering is used to determine which port wins arbitration. Note that when the ports are paired, their scan order can never be altered and they will always remain together in the scan order. Their counters increment together, and so when they reach their relative priority value, the port pair will dynamically be placed at the bottom of the scan order for that priority group.

In order for port weight sharing to be used, the relative priority parameters for the port pair must be programmed to the same value and the port order of the paired ports should be sequential. If either condition is not followed, an error bit will be set to 'b1.

Consider System G as described in Table 34-212. Again, for simplification, the command queue is considered to never be full, commands from ports 0, 1, 2 and 3 are only received at priority level 0 and commands from ports 4 and 5 are always at priority 1. However, now ports 0 and 1 and ports 4 and 5 are paired.

Table 34-212. System G Specifications

Memory Controller bits	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5
AXIY_PRI0_RELPRI	4	3	2	1	1	1
AXIY_PRI1_RELPRI	1	1	1	1	2	1
AXIY_P_ODR	0	1	2	3	4	5
W_RR_WSHR	1 (Paired)		0 (Not Paired)		1 (Paired)	

Table 34-213 shows the system behavior with port pairing. Since ports 4 and 5 are still at a lower priority, they will be ignored unless none of the higher priority ports (P0, P1, P2 or P3) are requesting. Note the following points:

- When either port of a port pair wins arbitration, the counters for both ports of the pair increment.
- In Cycle 3, the port pair P0/P1 reaches its allocated relative priority. Note that the port pair dynamically moves to the bottom of the scan order.
- In Cycle 8, the port pair P4/P5 reaches its allocated relative priority. However, since these are the only requests at priority 1, the scan order does not change.

Table 34-213. System G Operation

Cycle	Ports Requesting P0	P1	P2	P3	P4	P5	Arbitration Winner	Next Counter P0	P1	P2	P3	P4	P5	Next Scan Order
														Priority 0: P0-P1-P2-P3 Priority 1: P5-P4
0	Y		Y				P0	1	1	0	0	0	0	P0-P1-P2-P3 P5-P4
1	Y		Y			Y	P0	2	2	0	0	0	0	P0-P1-P2-P3 P5-P4
2			Y			Y	P2	2	2	1	0	0	0	P0-P1-P2-P3 P5-P4

Table continues on the next page...

Table 34-213. System G Operation (continued)

Cycle	Ports Requesting						Arbitration Winner	Next Counter						Next Scan Order
	P0	P1	P2	P3	P4	P5		P0	P1	P2	P3	P4	P5	
3	Y	Y		Y		Y	P0	3	3	1	0	0	0	P2-P3-P0-P1 P5-P4
4		Y		Y		Y	P3	0	0	1	1	0	0	P2-P3-P0-P1 P5-P4
5		Y		Y		Y	P3	0	0	1	2	0	0	P2-P0-P1-P3 P5-P4
6		Y				Y	P1	1	1	1	0	0	0	P2-P0-P1-P3 P5-P4
7						Y	P5	1	1	1	0	1	1	P2-P0-P1-P3 P5-P4
8					Y		P4	1	1	1	0	2	2	P2-P0-P1-P3 P5-P4
9					Y	Y	P5	1	1	1	0	1	1	P2-P0-P1-P3 P5-P4
10		Y	Y		Y	Y	P2	1	1	2	0	1	1	P0-P1-P3-P2 P5-P4
11		Y			Y	Y	P1	2	2	0	0	1	1	P0-P1-P3-P2 P5-P4

34.6.3.9 Error Conditions

With the programming complexities of the weighted round-robin arbitration scheme, an error reporting mechanism is included to notify users of illegal programming scenarios. These error conditions will each set a bit in the DDR_CR120[WRR_ERR] to 'b1. The potential error conditions are:

- Bit 0 = The 2 *axiY_p_odr* bits do not all contain unique values.
- Bit 1 = Any of the *axiY_priz_relpri* bits have been programmed with a zero value. A 0 value leads to unknown behavior. The minimum allowable value is 1.

- Bit 2 = Any ports, whose related bit of the DDR_CR120[W_RR_WSHR] is set to 'b1, do not have the same values in their *axiY_priz_relpri* bits.
- Bit 3 = For ports whose related bit of the W_RR_WSHR bit is set to 'b1, the values of the *axiY_p_odr* bits are not sequential.

If bit 0, 2 or 3 is set to 'b1 in the WRR_ERR, and any of the ports are paired in the W_RR_WSHR, then all weight sharing data will be ignored during Memory Controller initialization and the ports will be prioritized by port number. If port pairing is not being used, but the bit 0 error condition is set to 'b1, then ports with a non-unique port ordering are prioritized by port number.

Note

The user is strongly cautioned against modifying the values of the port ordering or relative priority parameters during active port usage.

34.6.3.10 Programmable Options for Weighted Round Robin Arbitration

The Memory Controller's weighted round-robin arbitration scheme provides a great deal of programmable control for the user. The parameters are referenced throughout this chapter and are summarized here for clarity:

- *axiY_r_pri* (DDR117[AXI0_R_PRI] and DDR118[AXI1_R_PRI])
- *axiY_w_pri* (DDR117[AXI0_W_PRI] and DDR118[AXI1_W_PRI])
- *axiY_priz_relpri* ((DDR120[AXI0_PRI1_RPRI], DDR120[AXI0_PRI0_RPRI], DDR121[AXI0_PRI3_RPRI],DDR121[AXI0_PRI2_RPRI], DDR122[AXI1_PRI1_RPRI], DDR122[AXI1_PRI0_RPRI], DDR123[AXI1_PRI3_RPRI] and DDR123[AXI1_PRI2_RPRI])
- *axiY_p_odr* (DDR121[AXI0_P_ODR] and DDR123[AXI1_P_ODR])
- *axiY_prirlx* (DDR122[AXI0_PRIRLX] and DDR124[AXI1_PRIRLX])
- DDR119[WRR_LATCTL]
- DDR120[W_RR_WSHR]
- DDR120[WRR_ERR]

34.6.4 Core Command Queue with Placement Logic

The MC core contains a command queue that accepts commands from the Arbiter. This command queue uses a placement algorithm to determine the order that commands will be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at the time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. In addition, the placement logic attempts to maximize efficiency of the MC core through command grouping, write-to-read splitting and bank splitting. Many of the rules used in placement may be individually enabled/disabled. In addition, the command queue may be disabled by clearing the DDR_CR75[PLEN] bit, resulting in an in-line queue that services requests in the order they are received. If the DDR_CR75[PLEN] is cleared to 'b0 and the DDR_CR79[INODR_ACT] is set to 'b1, the placement algorithm will be ignored.

34.6.4.1 Rules of the Placement Algorithm

The factors affecting command placement all work together to identify where a new command fits into the execution order. They are listed in order of importance.

34.6.4.1.1 Address Collision/Data Coherency Violation

The order in which read and write commands are processed in the memory controller is critical to proper system behavior. While reads and writes to different addresses are independent and may be re-ordered without affecting system performance, reads and writes that access the same address are significantly related. If the port requests a read after a write to the same address, then repositioning the read before the write would return the original data, not the changed data. Similarly, if the read was requested ahead of the write but accidentally positioned after the write, then the read would return the new data, not the original data prior to being overwritten. These are significant data coherency mistakes.

To avoid address collisions, reads or writes that access the same chip select, bank and row as a command already in the command queue will be inserted into the command queue after the original command, even if the new command is of a higher priority. This rule is ignored when comparing a new read command to an existing read. Even if an address collision occurs between these reads, there is no data integrity issue and the data may be returned in any order.

This factor may be enabled/disabled through the DDR_CR74[ADDR_CMP_EN] and should only be disabled if the system can guarantee coherency of reads and writes.

34.6.4.2 Source ID Collision

Each port is assigned a specific source ID that is a combination of the port and thread ID information, and identifies the source uniquely. This allows the memory controller to map data from/ to the correct source/destination.

Note that a source ID does contain port identification information which means that the rules for placement are dependent on the requesting port. There will not be source ID collisions between ports.

In general, read commands from the same source ID will be placed in the command queue in order. Therefore, a read command with the same source ID as a read command already in the command queue will be processed after the original read command. All write commands from a port, even with different source IDs, will be executed in order.

The behavior of commands of different types from the same source ID is dependent on the user configuration. For this Memory Controller, the placement of new read/write commands that collide in terms of source ID with existing entries in the command queue will only depend on other commands of the same type, not on different types. This means that, if there are no address conflicts, a read command could be executed ahead of a write command with the same source ID, and likewise a write command could be executed ahead of a read command with the same source ID.

This feature will always be enabled.

34.6.4.3 Priority

Priorities are used to distinguish important commands from less important commands. Each command is given a priority based on the command type through the programmable bits DDR_CR117[AXI0_R_PRI] and DDR_CR118[AXI1_W_PRI].

The placement algorithm will attempt to place higher priority commands ahead of lower priority commands, as long as they have no source ID or address collisions. Higher priority commands will be placed lower in the command queue if they access the same address, are from the same requestor or use the same buffer as lower priority commands already in the command queue.

This feature is enabled through the DDR_CR75[PRI_EN].

34.6.4.4 Bank Splitting

Before accesses can be made to two different rows within the same bank, the first active row must be closed (pre-charged) and the new row must be opened (activated). Both activities require some timing overhead; therefore, for optimization, the placement logic will attempt to insert the new command into the command queue such that commands to other banks may execute during this timing overhead. The placement of the new commands will still follow priority, source ID and address collision rules.

This feature is enabled through the DDR_CR74[BANKSPLT_EN].

34.6.4.5 Write-to-Read Splitting

When a read command follows a write command to the same chip select, there is some timing overhead to switch command types. For optimization, the placement logic will attempt to insert the new command into the command queue to separate two commands addressing the same chip select of different types where the write is going to execute before the read. The placement of the new commands will still follow priority, source ID and address collision rules. This feature is enabled through the DDR_CR76[W2R_SPLT_EN].

34.6.4.6 Read/Write Grouping

The memory suffers a small timing overhead when switching from read to write mode. For efficiency, the placement logic will attempt to place a new read command sequentially with other read commands in the command queue, or a new write command sequentially with other write commands in the command queue. Grouping will only be possible if no priority, source ID or address collision rules are violated. This feature is enabled through the DDR_CR75[RW_EN].

34.6.4.6.1 Bank Conflicts and Read/Write Grouping

If the new command addresses the same chip select and same bank, but a different row, as a command currently in the command queue, these commands are considered to have a bank conflict. As described in Bank Splitting, the placement logic will attempt to separate commands with bank conflicts. For this memory controller, certain placements are prohibited for read/write grouping to support ideal bank splitting.

These checks are controlled through the DDR_CR76[D_RW_G_BKCN]. If bit [0] of this parameter is set to 'b1, a new command will be prohibited from placement in the entry directly before or directly after the command with a bank conflict. If bit [1] of this parameter is also set to 'b1, the new command will also be prohibited from being placed two entries before or two entries after the command with a bank conflict. The following table shows a simplified command queue.

Table 34-214. Simple Command Queue Example

PQ Entry	Read/write	Bank	Row
0	Rd	0	0
1	Rd	0	0
2	Rd	0	0
3	Rd	1	0
4	Rd	0	0
5	Rd	0	0

For this example, a new entry is received that is a READ to BANK 1, Row 1. Assume that no priority, source ID or address collision rules are violated. This new command would have a bank conflict with PQ Entry 3.

- If D_RW_G_BKCN [0] = 'b1, the new command could not placed immediately before or after the conflicting command. If the command was placed into entry 3, entries 3-5 would be moved to entries 4-6, and the bank conflicts would occur between entries 3 and 4. If the command was placed into entry 4, entries 4-5 would be moved to entries 5-6 and the bank conflict would still occur between entries 3 and 4. Therefore, entries 3 and 4 are prohibited for placement.
- If D_RW_G_BKCN [1] = 'b1, the new command could not placed two entries before or two entries after the conflicting command. If the command was placed into entry 2, entries 2-5 would move to entries 3-6, and the bank conflict would occur between entries 2 and 4. If the command was placed into entry 5, the bank conflict would occur with between entries 3 and 5. Therefore, entries 2 and 5 are also prohibited for placement.
- Therefore, if the D_RW_G_BKCN bit was set to 'b11, the new entry could only be placed at entry 0, 1 or 6, allowing at least 2 commands in between the conflicting commands.

Note

It is not meaningful to set bit [1] of the DDR_CR76[D_RW_G_BKCN] without bit [0].

34.6.4.6.2 Chip Select Grouping with Read/Write Grouping

When attempting to group read and write commands, the placement logic will also consider the chip select for the commands. If possible, read commands will be grouped with read commands to the same chip select, and write commands with write commands to the same chip select. If chip select grouping is not possible, commands will still be grouped by command type if the DDR_CR75[RW_EN] is set to 'b1. If read/write grouping is disabled (DDR_CR75[RW_EN] is cleared to 'b0), chip select grouping will have no effect. This feature is enabled through the DDR_CR76[CS_EN].

34.6.4.6.3 Page Grouping with Read/Write Grouping

When attempting to group read and write commands, the placement logic will also consider the page for the commands. If possible, read commands will be grouped with read commands to the same page, and write commands with write commands to the same page. If page grouping is not possible, commands will still be grouped by command type if the DDR_CR75[RW_EN] is set to 'b1. If read/ write grouping is disabled (DDR_CR75[RW_EN] is cleared to 'b0), page grouping will have no effect. This feature is enabled through the DDR_CR75[RW_PG_EN] parameter.

34.6.4.7 Command Execution Order After Placement

Once a command has been placed in the command queue, selection logic will be used to determine how to pull commands from the queue for execution. This logic may be disabled by setting the DDR_CR79[INODR_ACT] to 'b1, resulting in the command queue executing the commands in the order that they are placed relatively in the command queue. If the DDR_CR79[INODR_ACT] is cleared to 'b0, the selection logic will be utilized. Regardless of the setting of this parameter, high-priority command swapping and command aging are provided which may affect commands after they have been placed into the command queue.

34.6.4.7.1 Command Selection Logic

On each clock cycle, the selection logic will scan the top 4 entries of the command queue to determine which command to execute. This value is defined at configuration. Commands are considered for execution based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing (JEDEC-specified and programmable) and conflicts. Similar to the placement rules, a command will not be executed before a command that was placed ahead of it in the command queue if there are any address, source ID or bank conflicts.

All placement rules mentioned in this chapter are followed by the selection logic other than priority. It is possible that lower priority commands may be executed ahead of higher priority commands if the higher priority commands are not ready to execute, provided that there are no conflicts with commands ahead in the command queue. The memory controller will also not execute a read/ modify/write sequence before another read/modify/write sequence ahead of it in the command queue due to limited storage in the core.

The selection feature is disabled through the DDR_CR79[INODR_ACT] . If this bit is set to 'b1, only the top entry of the command queue will be considered for execution. The following figure shows the command selection logic relative to the rest of the placement logic.

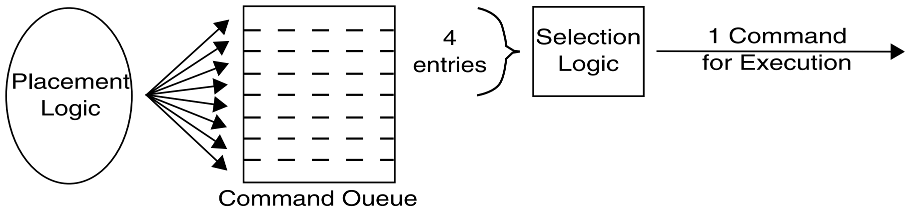

Figure 34-195. Selection logic

34.6.4.7.2 High-Priority Command Swapping

Commands are assigned priority values to ensure that critical commands are executed more quickly in the memory controller than less important commands. Therefore, it is desirable that high-priority commands pass into the MC core as soon as possible. The placement algorithm takes priority into account when determining the order of commands, but still allows a scenario in which a high-priority command sits waiting in the command queue while another command, perhaps of a lower priority, is in process. The high-priority command swapping feature allows this new high-priority command to be executed more quickly. If the user has enabled the swapping function through the DDR_CR79[SWAP_EN] parameter, then the behavior of the swapping logic will be dependent on the value of the DDR_CR79[INODR_ACT]. If the command queue must be executed in order (INODR_ACT = 'b1), the entry at the top of the command queue will be compared with the current command in progress. If the selection logic is being used (INODR_ACT = 'b0), the top 4 entries of the command queue will be compared with the current command in progress to determine which command may need to be executed first. If the selected command queue entry is of a higher priority (not the same priority), from a different ID, and it does not have an address or source ID conflict with the current command being executed, then the original command will be interrupted. If the command is to be interrupted, it will be halted after completing the current burst, stored and placed at the top of the command queue, and the new command will begin executing. As long as the command queue is not full, new commands may continue to be

inserted into the command queue based on the placement rules, even at the top of the queue ahead of the interrupted command. The selection logic will determine the command to execute next. Whenever the interrupted command is resumed, it will start from the point at which it was interrupted. Note that priority 0 commands will never be interrupted, so the user should set any commands that should not be interrupted to priority 0.

34.6.4.7.3 Command Aging

Since commands can be inserted ahead of existing commands in the command queue, the situation could occur where a low priority command remains at the bottom of the queue indefinitely. To avoid such a lockout condition, aging counters have been included in the placement logic that measure the number of cycles that each command has been waiting. If an aging counter hits its maximum, the priority of the associated command will be decremented by one (lower priority commands are executed first). This increases the likelihood that this command will be picked by the selection logic and execute. Note that this command does not move relative positions in the command queue when it ages; the new priority will be considered when placing new commands into the command queue.

Aging is controlled through a master aging counter and command aging counters associated with each command in the command queue. The DDR_CR74[AGE_CNT] and DDR_CR74[CMD_AGE_CNT] hold the initial values for each of these counters, respectively. When the master counter counts down the AGE_CNT bit value, a signal is sent to the command aging counters to decrement. When the command aging counters have expired, the priority of the associated command is decremented and the counter is reset. Therefore, a command does not age by a priority level until the total elapsed cycles has reached the product of AGE_CNT bit value+ 1 and CMD_AGE_CNT bit value + 1. The maximum number of cycles that any command can wait in the command queue until reaching the top priority level is the product of the AGE_CNT bit value +1, the CMD_AGE_CNT bit value +1, and the number of priority levels in the system.

If command swapping is enabled, it is possible that a command in progress could be interrupted by a higher priority command in the command queue. This situation could arise if a new higher-priority command arrives and is placed while the current command is in progress, or by a command in the queue aging to a lower priority while the current command is in progress. An interrupted command will be placed at the top of the command queue.

This feature will always be enabled.

34.6.4.8 ACT Request Control

The Memory Controller provides a means to limit which commands of the command queue may issue ACT requests. This can be used to prevent situations in which an ACT is issued for a command in the queue, and before that command can be executed, a new command is placed ahead of it which accesses the same bank but a different row. This would require a PRE-ACT sequence that may have been avoided if the first ACT was never issued.

This functionality is controlled through the DDR_CR76[NQENT_ACTDIS], which specifies the number of entries of the command queue in which ACT requests are not allowed. For this 8-deep command queue, the entries are numbered 0-7, where entry 0 is the command next to execute.

Table 34-215. Programming of the NQENT_ACTDIS bits

Value	Effect
0x0	ACT request can occur from entries 0-7
0x1	ACT request can occur from entries 0-6
0x2	ACT request can occur from entries 0-5
0x3	ACT request can occur from entries 0-4
0x4	ACT request can occur from entries 0-3
0x5	ACT request can occur from entries 0-2
0x6	ACT request can occur from entries 0-1
0x7	ACT request can occur from entries 0

34.6.5 ECC Options

Memory Controllers provide an optional error reporting and correcting circuitry that can be used to verify data in memory and correct memory errors if they occur. The logic will check for errors in both the data and the check code on all read transactions.

ECC, or error checking and correcting, is the process of detecting bit errors in the memory data and if possible, correcting them. This function can confirm the accuracy of data and remove or at least identify bit errors.

ECC works by storing unique "check codes" in memory. A check code is a mathematical description of the information in an aligned segment of memory known as an "ECC data word". The check code is always related to the entire ECC data word, and is used inside the Memory Controller on all memory reads to control data accuracy. Check codes are not input from, or output to, the user interface.

An ECC data word can not start and end at any random address; these words are memory aligned to their size. The starting addresses of ECC data words are defined as ECC word boundaries and the alignment of user transactions to these boundaries determines how transactions are processed inside the Memory Controller. If the user does not wish to use the ECC option, the ECC module may be disabled by setting the control bit DDR_CR57[CTRL_RAW] to 'b10.

This Memory Controller supports a 32-bit ECC data word size. A 7-bit check code is maintained for each 32-bit memory area. ECC word boundaries fall on each 4-byte address (0xN0, 0xN4, 0xN8, 0xNc).

34.6.5.1 Initialization of memory when using ECC

When using ECC, or error checking and correcting,additional steps are required to configure the memory and all ECC values after the controller has been initialized.

The entire memory region that will be used should be written once. This write is required so that a correct ECC tag can be written for each memory location. There are two recommended methods for performing this initialization.

- Using the DMA to initialize the memory.

  The DMA controller is usually the most efficient means of writing the initial data and ECC values to the memory. The DMA should be configured to perform a 32-byte write to DDR destination addresses with the NBYTES field configured so that any memory locations that will be used by the system are initialized.

- Using the CPU to initialize the memory.

  A CPU can also be used to write the initial data and ECC values to memory; however, when using a CPU to perform the writes the accesses can actually trigger ECC errors. To avoid this, set the DDRMC_CR058[ECC_DIS_WCRER] bit, then perform the writes to set the initial values. After all of the memory locations have been initialized, the ECC_DIS_WCRER bit can be cleared.

34.6.6 Low Power Operation

The Memory Controller provides various user-configurable low power options to address power savings.

There are seven low power states available in the Memory Controller and managed by the LPC module. The low power states are listed from least to most power saving.

Note

Transitions will only be made into deeper low power states. If the user requires to switch to a higher power state, the current state must be exited and then the new state entered.

Note

Low power state transitions that may be completed without a low power exit will be performed when possible. The system will include low power exits if necessary when switching from one low power state to another. Low power modes entry exit is controlled through the register interface

1. Active Power-Down

   The memory controller sets the memories into power-down while any row is active in the bank. This state reduces the overall power consumption of the system, but has the least effect of all the low power states. In this state, the memory controller and memory clocks are fully operational, but the CKE input bit to the memories is de-asserted. If entry into the "Active Power-Down" state was requested, the memory will enter either active or pre-charge power-down mode depending on the state of the rows. If there are no open rows, pre-charge power-down mode will be entered. If the DDR_CR34[LP_REFEN] is set to 'b1, the memory controller will continue to monitor memory refresh needs and will automatically bring the memory out of power-down to perform these refreshes. When a refresh is required, the CKE input bit to the memories will be re-enabled. This action brings the memories out of power-down. Memory that has been transitioned into active power-down mode will automatically transition to pre-charge power-down mode after the memory controller performs a refresh since the refresh process includes a pre-charge all command.

2. Active Power-Down with Memory Clock Gating

   The memory controller sets the memories into power-down while any row is active in the bank, and gates off the clock to the memories. Refreshes will be handled as in the "Active Power-Down" state, with the exception that gating on the memory clock will be removed before asserting the CKE pin. Memory that has been transitioned into active power-down mode will automatically transition to pre-charge power-down mode (with the clock gated) when the memory controller performs a refresh since the refresh process includes a pre-charge all command. Before the memories are removed from power-down, the clock will be gated on again.

This low power state is only valid for LPDDR2 memory. The user should not use this state for memories that do not support memory clock gating. Clock gating is not supported for standard DDR3 memories. When set into this state, the memory controller will attempt to place the memories in power-down and gate off the memory clock. The memory will function unpredictably and may hang.

3. Pre-Charge Power-Down

   The memory controller sets the memories into power-down once all banks are idle. If any rows are active, prior to issuing the power-down mode command, the memory controller will issue a pre-charge all command. If the DDR_CR34[LP_REFEN] is set to 'b1, the memory controller will continue to monitor memory refresh needs and will automatically bring the memory out of power-down to perform these refreshes. When a refresh is required, the CKE input bit to the memories will be re-enabled. This action brings the memories out of power-down. Once the refresh has been completed, the memories will be returned to pre-charge power-down mode following the de-assertion the CKE input bit. For DDR3, pre-charge power-down mode supports both fast and slow exit modes depending on how the memory mode registers are programmed. If the pre-charge power-down bit (MR0 [A12]) is cleared to 'b0 (slow exit), the timing parameter *txpdll_fN* will define the exit time from this low power state to a read command. If the pre-charge power-down parameter is set to 'b1 (fast exit), the timing parameter *tpdex_fN* will be used.

4. Pre-Charge Power-Down with Memory Clock Gating

   The memory controller sets the memories into power-down once all banks are idle, and gates off the clock to the memories. Refreshes will be handled as in the "Pre-Charge Power-Down" state, with the exception that gating on the memory clock will be removed before asserting the CKE pin. After the refresh has been completed, the memories will be returned to pre-charge power-down mode with the clock gated. Before the memories are removed from power-down, the clock will be gated on again. This low power state is only valid for LPDDR2 memory.

   The user should not use this state for memories that do not support memory clock gating. Clock gating is not supported for standard DDR1, DDR2 or DDR3 memories. When set into this state, the memory controller will attempt to place the memories in power-down and gate off the memory clock. The memory will function unpredictably and may hang.

5. Self-Refresh

The memory controller sets the memories into self-refresh mode. In this low power mode, the memory controller and memory clocks are fully operational and the CKE input bit to the memories is de-asserted. Since the memory automatically refreshes its contents, the memory controller does not need to send explicit refreshes to the memory.

6. Self-Refresh with Memory Clock Gating

   The memory controller sets the memories into self-refresh and gates off the clock to the memories. Before the memories are removed from self-refresh, the clock will be gated on again. This low power state is only valid for LPDDR2 memory.

7. Self-Refresh with Memory and Controller Clock Gating

   This is the deepest low power state of the memory controller. The memory controller sets the memories into self-refresh and gates off the clock to the memories. In addition, the clock to the memory controller will be gated off.

   Before the memories are removed from self-refresh, the memory controller and memory clocks will be gated on. If automatic exit from this state is enabled, a new transaction that addresses a memory device in this state will wake up the memory to process the transaction. This low power state is only valid for LPDDR2 memory.

Note

This state should not be entered when a read or write command is being processed. The user should ensure that the controller is idle before requesting entry into this state by checking the DDR_CR79[CTLBUSY].

Note

When the controller clock is gated through the low power control module, writes to any of the programmable command parameters - parameters that result in command execution within the controller - will be ignored and not result in execution of the associated commands. Any commands issued while the controller clock is gated may or may not be executed once the controller clock is un-gated. In general, command registers should not be programmed during controller clock gating as the commands will have undefined results.

34.6.6.1 Automatic Interface

The LPC module supports automatic entry into each of the low power states based on programmable enables and idle state monitors. Each low power state has a separate enable bit and counter. As with the external pin interface and software programmable interface, the automatic interface must win arbitration of the LPC module to issue requests. The automatic interface has the lowest priority for arbitration.

When the memory controller is idle, each of the seven timing counters that are enabled begin counting down the cycles of inactivity. Idle time requires that no read or write commands are executing or pending in the memory controller core command queue or any of the ports. For the power-down states, idle time begins when no commands are waiting to be sent to memory. For the self-refresh states, idle time begins only after all the read data for outstanding read commands has been retrieved; this restriction ensures that all read data is received even if the automatic request includes gating off the memory controller clock.

34.6.6.1.1 Automatic Entry

If any of the counters expire, the automatic interface will request arbitration. The timing counters are initially loaded with the values in the associated parameters, and will only decrement if the associated DDR_CR36[LPAUTO] parameter bit is set to 'b1 and the counters are loaded with a non-zero value. If no other interface has control of the LPC module (DDR_CR35[LP_ARBST] = 'b00 or 'b11), the automatic interface will win arbitration and the specified low power state will be compared to the current state of the memories. If the memory is already in a low power state, and the expired counter is associated with a deeper low power state than the current state, the LPC module will trigger an entry into the new low power state. If the expired counter is associated with a higher power usage state, the counter expiration will be ignored.

If a counter expires while the LPC module is being controlled by the external pin interface or the software programmable interface, the automatic request will remain pending until the arbiter returns to idle (LP_ARBST = 'b00) and the automatic interface is granted control of the LPC module. A pending request will also be cancelled if a read or write command enters the Memory Controller core command queue, resetting the automatic counters to the programmed values.

Multiple automatic low power idle counters may expire at the same time. When this happens, the counter associated with the deepest low power state will be entered. No state change will occur if current low power state is deeper than the states associated with any of the expired counters.

34.6.6.1.2 Automatic Exit

The automatic interface also supports automatic exit from a low power state if the system requires, with separate enable bits for each low power state. During an automatic exit, all of the idle counters are reset to their programmed values and the memories are returned to normal operation. When a new read or write command enters the memory controller command queue, if the current low power state's associated DDR_CR36[LP_AEXEN] is set to 'b1, the automatic interface will request arbitration. If no other interface has control of the LPC module ((DDR_CR35[LP_ARBST] = 'b00 or 'b11), the automatic interface will win arbitration and a low power exit will be triggered. If the current state is not enabled for automatic exit in the DDR_CR36[LP_AEXEN], the LPC module will not exit low power.

If the LPC module is being controlled by the external pin interface or the software programmable interface when the new read or write command appears, the automatic request will remain pending until the arbiter returns to idle ((DDR_CR35[LP_ARBST] = 'b00) and the automatic interface is granted control of the LPC module.

Only new read or write commands will cause the counters to be reloaded to their programmed values and trigger an exit. Other commands, including MRR, MRW, low power entry and exit commands, register accesses, refresh, ZQ, etc., do not reset the counters and do not trigger an exit from low power. When the memory controller is idle and the memories have automatically entered a low power state, these commands may be prevented from executing.

It is generally expected that any state that is defined for automatic entry DDR_CR36[LPAUTO] should also be enabled for automatic exit DDR_CR36[LP_AEXEN]. Automatic exit may also be used for low power states that are not defined for automatic entry, but are expected to be entered manually through the software programmable interface DDR_CR35[LP_CMD]. If it is desirable to use both manual and automatic entry/ exit into the same low power state, then the user may need to re-program the DDR_CR36[LP_AEXEN] parameter prior to issuing a request through the software programmable interface.

34.6.6.2 Refresh Masking

Regular refresh commands will be issued at the same intervals while the memory controller is operating normally, is idle, or is in any of the low power states. However, for memory arrays with multiple chip selects, the Memory Controller supports the ability to mask refreshes while in any of the power-down low power states. By setting bits of the DDR_CR34[LP_REFEN] parameter to 'b1, auto-refreshes will be masked for the associated chip selects.

It is the user's responsibility to ensure that refreshes are not constantly masked, and that each chip select is refreshed periodically.

34.6.6.3 Mobile DDR SDRAM Memories

34.6.6.3.1 Enabling Mobile Usage

When using a mobile memory, bit 0 of the DDR_CR00[DRAM_CLASS] must be set to 1. This enables the memory controller to use the initialization sequence and mode register addressing appropriate to mobile memories. When bit 0 of the DDR_CR00[DRAM_CLASS] is cleared to 'b0, a standard DDRSDRAM or SDRAM memory may be used.

34.6.6.3.2 Partial Array Self-Refresh

For mobile memories, the Memory Controller is capable of supporting refreshes to subsections of the memory array. To facilitate this capability, separate parameters are provided to supply the mode register data for each chip select. These parameters are named *mrY_data_X*, where X represents the chip select and Y represents 0, 1, 2 or 3 - depending on the memory type being used.

Having separate control parameters for the mode register data allows the individual chips to set their own masked refresh. The DDR_CR45[WRMD] controls the writing of this mode register data into the registers. When the DDR_CR45[WRMD] is set to 'b1 initially, the mode register of chip select 0 will be written. Each subsequent setting of the DDR_CR45[WRMD] to 'b1 will write the mode register of the next chip select (1, 2, 3, etc.).

Note that the memory controller does not check if operations attempt to access addresses outside of the refresh ranges set by the memory mode registers. Any accesses to these addresses may result in corrupt or lost data.

34.6.7 Out-of-Range Address Checking

It is possible that the master attempts to write to an invalid address. For this reason, all incoming addresses are always checked against the addressable physical memory space. If a transaction is addressed to an out-of-range memory location, then bit 1 of the DDR_CR80[INT_STAT] will be set to 'b1 to alert the user of this condition. The memory controller will record the address, source ID, length and type of transaction that caused the out-of-range interrupt in the DDR_CR83[OORAD], DDR_CR84[OORID], DDR_CR84[OORLEN] and DDR_CR84[OORTYP].

Reading the out-of-range parameters will initiate the Memory Controller to empty these parameters and allow them to store out-of-range access information for future errors. The interrupt should be acknowledged by setting bit 1 of the DDR_CR81[INT_ACK] parameter to 'b1, which will in turn cause bit 1 of the DDR_CR80[INT_STAT] to be cleared to 'b0.

If a second out-of-range access occurs before the first out-of-range interrupt is acknowledged, then bit 2 of the DDR_CR80[INT_STAT] will be set to 'b1 to indicate that multiple out-of-range accesses have occurred. If the out-of-range parameters have been read when the second out-of-range error occurs, then the details for this transaction will be stored in the out-of-range parameters. If they have not been read, then the details of the second error will be lost.

Even though the address has been identified as erroneous, the Memory Controller will still process the read or write transaction. A read transaction will return random data which the user must receive to avoid stalling the memory controller.A standard, non-exclusive write transaction will write the associated data to an unknown location in the memory array, potentially over-writing other stored data. A command can not be aborted once accepted into the Memory Controller.

A special situation occurs with AXI exclusive accesses. For an exclusive write access only, if the exclusivity check fails, then the command will automatically be flushed internally. This is the only situation in which the erroneous data is NOT written to memory but is cleared out of the memory controller FIFOs. The DDR_CR84[OORTYP] bits [5:4] maintain status on AXI exclusive accesses.

Table 34-216. Out of Range Access Parameter

Memory Controller bit	Description
DDR_CR83[OORAD][31:0] Out of range address	Transaction Address
DDR_CR84[OORID] [13:0] Out of range source id	Bits [13:13] = Port ID Bits [12:0] = AXI Thread ID
DDR_CR84[OORLEN] [6:0] Out of range length	Total byte count of the transaction. • For write commands: (AXI port Y encoded write command length + 1) x $2^{(\text{AXI port Y encoded write command size})}$. • For read commands: (AXI port Y encoded read command length + 1) x $2^{(\text{AXI port Y encoded read command size})}$.

Table continues on the next page...

Table 34-216. Out of Range Access Parameter (continued)

Memory Controller bit	Description
DDR_CR84[OORTYP] [5:0] Out of range type	• 'b000000 = Non-Exclusive Write • 'b000001 = Non-Exclusive Read • 'b000010 = Non-Exclusive Masked Write • 'b000100 = Wrapped Write • 'b000101 = Wrapped Read • 'b000110 = Wrapped Masked Write • 'b001000 = Exclusive Write • 'b001001 = Exclusive Read • 'b001010 = Exclusive Masked Write • 'b010000 = Flushed Write • 'b100000 = Non-Exclusive Write with Auto-Precharge • 'b100001 = Non-Exclusive Read with Auto-Precharge • 'b100010 = Non-Exclusive Masked Write with Auto- Precharge • 'b100100 = Wrapped Write with Auto-Precharge • 'b100101 = Wrapped Read with Auto-Precharge • 'b100110 = Wrapped Masked Write with Auto-Precharge • 'b101000 = Exclusive Write with Auto-Precharge • 'b101001 = Exclusive Read with uto-Precharge • 'b101010 = Exclusive Masked Write with Auto-Precharge • 'b110000 = Flushed Write with Auto-Precharge • All other settings Reserved

34.6.8 Command to Command Timing

For flexibility and maximum user control, the Memory Controller provides a set of timing parameters to control the bus turnaround timing between commands of different types. In many systems, the extended pad or board delays may cause interference with the timings defined by default when changing chip selects or command types. These parameters allow the user to add additional cycles between a particular command combination by increasing the associated command to command parameter value based on the application-specific delay implementation. Each of the command to command parameters listed below can be changed individually to achieve timing which does not cause bus contention. The user should program each parameter with the actual number of clocks of turn-around required for this transaction combination on the data bus.

The memory controller accounts for the burst length and memory timing requirements. These command to command parameters do not compensate for these delays, but rather should be used to account for any additional delay needed such as variance in the pads, board or system. Also, more delay may be needed to turn the bi-directional DQ/DQS bus around for commands of different types for example if pad enable and disable times are different and additional time may be required to complete the turnaround. Or more time may be needed to account for variance in delays between different ranks. The "samecs" parameters may also be used to account for termination timing.

These command to command parameters should also be used to account for any constants in the timing equations in the JEDEC specification. For example, the LPDDR2 specification lists the R2W same CS delay as:

RL + tDQSCK_MAX + BL/2 + 1 - WL

The memory controller will account for all of these terms, other than the "+1". Therefore, for this memory system, the R2W_SMCSDL parameter would need to be programmed to at least a value of 0x1.

The command to command bits are:

- DDR_CR89[AODT_WRSMCS]
- DDR_CR89[AODT_RWSMCS]
- DDR_CR91[R2R_SMCSDL]
- DDR_CR91[R2W_SMCSDL]
- DDR_CR91[W2R_SMCSDL]
- DDR_CR92[W2W_SMCSDL]

34.6.9 Writing Mode Registers

The Memory Controller provides several options to program the mode registers in the memories. This functionality is controlled through the DDR_CR45[WRMD]. The encoding of this parameter defines which mode register(s) and which chip select(s) will be written. When the write has been completed (or if an invalid request was programmed), the mode register write complete interrupt (bit 21) will be set in the DDR_CR80[INT_STAT]. Any errors will be reported in the DDR_CR46[MRW_STAT] parameter. This parameter will be reset to 0x0 on the cycle after it is changed and can not be reprogrammed until the interrupt occurs.

34.6.9.1 WRMD (write mode register) bit fields

The fields of the DDR_CR45[WRMD] are:

- Bit [25] = Trigger the MRW sequence with the settings defined in bits [24:0].
- Bit [24] = Write all chip selects
  - 'b0 = Only the chip select identified in bits [15:8] will be written for the mode register(s) specified in bits [23:16].
  - 'b1 = Bits [15:8] will be ignored and all chip selects will be written for the mode register(s) specified in bits [23:16].
- Bits [23:16] = Mode register write type. Only one of these bits should be set when bit [25] is set. If no bits are set, an error will be flagged in the DDR_CR46[MRW_STAT]. If bit [24] is set to 'b1, all chip selects will be programmed. If bit [24] is cleared to 'b0, bits [15:8] will specify which chip select will be programmed.

  As shown in Table 34-217, the memory controller may provide mode register parameters that have no meaning for a particular memory system or chip select. If the user attempts a write to a mode register that is not relevant to the memory system for which the MC is programmed (through the DDR_CR00[DRAM_CLASS] parameter), the memory controller will only perform the write when applicable. For example, an all-chip select write to MR16 and MR17 will only write these mode registers when programmed for LPDDR2 memory systems.

  - Bit [23] = Write a single MRz

  The mode register specified in bits [7:0] will be written with the data in the associated mrsingle_data_X parameters. Even if an associated mrZ_data_X parameter exists (refer to Table 34-217), the data from that parameter will NOT be used for the write and the mrZ_data_X parameter will not be updated with this command. This setting can be used to write mode registers for which the Memory Controller does not provide a specific parameter.

  - Bit [18] = Write MR16, MR17
  - Bit [17] = Write MR0, MR1, MR2, MR3
  - All other bits reserved

- Bits [15:8] = Chip select number to be written. This field is only valid when bit [24] is cleared to'b0 specifying that only a single MRz will be written.
- Bits [7:0] = Mode register number to be written. This field is only valid when bit [23] is set to 'b1 specifying that only a certain MRz will be written.

  The mode register write(s) will be issued when the trigger bit (bit [25]) is set. Once the memory controller has completed all of the writes, the mode register write complete interrupt (bit 21) will be set in the DDR_CR80[INT_STAT] and errors will be reported in the DDR_CR46[MRW_STAT]. The DDR_CR45[WRMD] will be reset to 0x0 on the cycle after it is changed.

  - Bit [16] = Write MR0, MR1, MR2, MR3, MR16, MR17

34.6.9.2 MRW Module and Arbiter

The mode register write (MRW) module initiates the required mode register writes for any memory type. These MRWs are initiated from several modules including the initialization state machine, frequency scaling logic, low power logic and software. Since requests originate from different sources, multiple MRW requests may occur at the same time. To manage these requests, the MRW module contains an arbiter. If multiple requests occur, they will be serviced in the following priority order:

- ZQ Calibration
- Hardware Frequency Changes (MRW to MR0, MR1 and MR2 in order for each memory)
- Power-on initialization
- Power-on MR0 for initialization of non-LPDDR2 memories
- Power-on DLL reset

If a lower priority request is being serviced when a higher priority request is issued, the lower priority request will complete entirely before the higher priority request will be serviced. This is true even if the request must write to multiple mode registers and/or multiple chip selects. Software will initiate MRWs by programming the DDR_CR45[WRMD].

34.6.9.3 Programming Errors

If the DDR_CR45[WRMD]r was programmed incorrectly, the memory controller state machine may or may not issue the request. In either case, the mode register write complete interrupt (bit 21) will be set to 'b1 in the DDR_CR80[INT_STAT] and then the DDR_CR46[MRW_STAT] should be read for error information. If any bits are set in this parameter, an error occurred. This is a read-only parameter, with the following bit settings:

- Bits [7:3] = Reserved
- Bit [2] = Reserved
- Bit [1] = A mode register write was requested for the PASR mode registers (MR16, MR17) when the memory controller is not programmed for LPDDR2 memory systems (DDR_CR00[DRAM_CLASS] is not set to 'b0101).
- Bit [0] = DDR_CR45[WRMD] programming error. This bit will be set if no mode register write type is specified (DDR_CR45[WRMD] bits [23:16]) but the mode register write was triggered (DDR_CR45[WRMD] bit [25] = 'b1).
- ZQ Calibration
- Hardware Frequency Changes (MRW to MR0, MR1 and MR2 in order for each memory)
- Power-on initialization
- Power-on MR0 for initialization of non-LPDDR2 memories
- Power-on DLL reset

34.6.9.4 Mode Register Storage in the Memory Controller

There are specific parameters in the register map to hold the date to write into the mode registers. The parameters that are not listed as read-only may be written at any time, and will be programmed into the memory mode registers when the DDR_CR45[WRMD] is programmed with the specified settings.

Table 34-217. Mode Register Parameters

Memory Controller Parameter	*write_modereg* Associated Mode Write Type Bit	Memory System Correlations	
MR0_DAFN_X	Bit [16] = 'b1 Bit [17] = 'b1	• LPDDR2 (S2): • LPDDR2 (S4): • DDR3:	MR0 (read-only) MR0 (read-only) MR0
MR1_DAFN_X	Bit [16] = 'b1 Bit [17] = 'b1	• LPDDR2 (S2): • LPDDR2 (S4): • DDR3:	MR1 MR1 MR1
MR2_DAFN_X	Bit [16] = 'b1 Bit [17] = 'b1	• LPDDR2 (S2): • LPDDR2 (S4): • DDR3:	MR2 MR2 MR2
MR3_DAX	Bit [16] = 'b1 Bit [17] = 'b1	• LPDDR2 (S2): • LPDDR2 (S4): • DDR3:	MR3 MR3 MR3

MR_SINDAX	Bit [23] = 'b1	-	

1. *There is no corresponding mode register for this memory system. Any attempt to write this mode register for this memory system will be ignored.*
2. *There is no corresponding mode register for this memory system. Any attempt to write this mode register for this memory system will be ignored.*
3. *This mode register should not be written for this memory system.*
4. *There is no corresponding mode register for this memory system. Any attempt to write this mode register for this memory system will be ignored.*

34.6.10 Refresh Per Command Timing

The *tref_fN* parameter is used to define the number of DRAM cycles allowed between refresh commands from the memory controller. This parameter sets the average interval between refreshes.

The actual interval may vary by up to 8 cycles from refresh to refresh, depending on other activities that are occurring in the controller at the time.

Over an infinite time period, the average interval will be equal to the number of clocks set by this parameter; however, if the user sets this parameter to be exactly equal to the specification value tREFi, then local variations might mean that the memory tREF value may be violated by a very small amount.

The amount of this violation would be 8tCK/tREF. For example, for a 400 MHz memory and tREF=64 ms, the amount of the violation would be 2.5 ns/64 ms = 0.000004%.

34.6.11 Mobile Memories DQS

For these memories, all accesses to memory must be memory burst-aligned in both address and length. The Memory Controller still processes all transactions even if the starting and/or ending address is unaligned. Therefore, for a x4 memory, a write that begins or ends on an unaligned address will result in memory corruption. Such an access may also result in taking more data from the write FIFO than what correlates to the current transaction.

34.6.12 Refresh Per Chip Select

While memory refresh operations are necessary for DRAM data integrity, they unfortunately draw a significant current and temporarily disable the memory from accepting other commands. A standard practice is to issue refresh commands to all chip selects simultaneously at each tref interval. This minimizes the downtime before another data command can be processed (trfc) but does increase peak current while the refresh is in progress.

As an alternative, the Memory Controller includes the option to individually refresh each chip select in a sequential manner. When using this feature, a memory refresh may be initiated from the user interface by setting the a refresh parameter to 'b1 or through an internal source such as the expiration of the tref_f0 counter or an exit from Self-Refresh.

Regardless of the source, when the refresh command is received, all transactions will be inhibited and a refresh sequence will be initiated. This refresh sequence issues refresh commands to one chip select at a time, moving through all of the chip selects in succession. A programmable delay (the tref_interval bit) sets the time period between when refresh commands are issued to different chip selects.

A related memory-specific bit (DDR_CR26[TRFC_F0]) sets the time that a DRAM memory must wait between receiving a refresh command to when a data transaction can be processed. When each refresh command is issued, the trfc counter inside the MC core begins a countdown from the programmed value (in the TRFC_F0 bit). With each refresh command, the counter is reset and the memory controller will only accept commands TRFC_F0 cycles after when the final refresh command has been issued. Once the TRFC _F0 time expires, normal read/write traffic and behavior resumes in the memory controller. All other transactions will be inhibited during this refresh sequence until all chip selects have been issued their refresh commands and the associated timing requirements have been met.

34.6.12.1 Programming of the *tref_f0* bits

The *tref_f0* bits sets the average interval between refreshes. The actual interval may vary by up to 8 cycles from refresh to refresh, depending on other activities that are occurring in the controller at the time. Over an infinite time period, the average interval will be equal to the number of clocks set by this bit; however, if the user sets this bit to be exactly equal to the specification value tREFi, then local variations might mean that the memory tREF value may be violated by a very small amount.

The amount of this violation would be 8tCK/tREF. For example, for a 400 MHz memory and tREF=64 ms, the amount of the violation would be 2.5 ns/64 ms = 0.000004%.

34.6.12.2 Programming of the tref_INT bits

The interval is a critical value in achieving real current savings. The following considerations should be taken for programming the DDR_CR28[TREF_INT] bits.

- A larger interval will increase the time that the memory controller is held off from processing data transactions.
- Peak current restrictions will guide the interval value. The interval should be defined to the minimum value that still meets peak current restrictions.
- Programming the interval to zero will disable the refresh per chip select logic and refresh commands will be issued simultaneously to all chip selects.

- The refresh per chip select logic requires at least one dead cycle between refresh commands, and therefore the minimum interval used is actually 4 cycles. Programming the TREF_INT bits to 1, 2 or 3 will default to 4 cycles.
- The Memory Controller runs at half the frequency as the memories. Therefore, if the TREF_INT bits is programmed to an odd number of clocks, the actual interval used will be the one clock longer than programmed
- Other factors in the design also affect timing, and therefore the actual delay between refresh commands may exceed the programmed value. This is particularly likely when the interval value programmed is very low, such as 'b004.
- When the t_{RFC} counter completes its countdown, the memory controller will accept any pending commands. Since no read or write commands may occur during the entire refresh sequence, the TREF_INT bits should always be set to a value lower than the TRFC_F0 bits.

Figure 34-196 shows a refresh sequence for a system with four chip selects and a TREF_INT of four clocks ('b100).

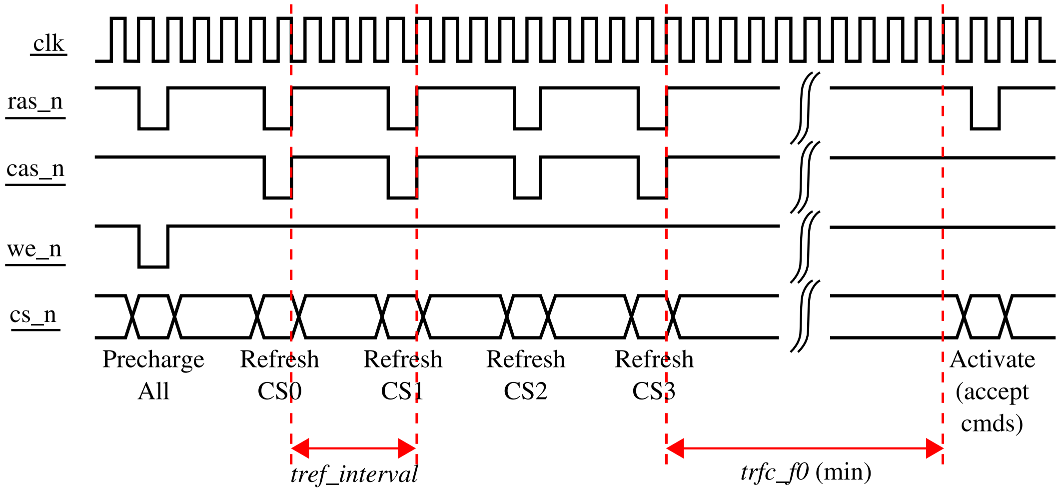

Figure 34-196. Refresh per CS Example

34.6.13 Half Data path option

The memory controller can be made to operate in half datapath mode (8 bit memory mode) through the register space with the option to enable ECC.

34.6.14 ZQ pad calibration

ZQ pad calibration logic handles the calibration of the drivers and termination resistances in DDR pads. The auto mode is handled by the logic on it's own and is the mode that would be used during functional operation of DDR. Software calibration can be used to override the pad calibration process. Software calibration is very slow and at best is useful for debug purposes.

When ZQ pad calibratrion is enabled in the DDR_CR154[PAD_ZQ_MODE], the calibration is done in parallel to the memory ZQ calibration. Pad calibration will either be done with both short and long ZQ calibration commands issued to the memory or only when long calibration is done (including during memory initial sequence and refresh exit). Memory controller must be separately programmed to control how it issues the ZQ calibration commands to the external memory.

There is provision to issue a separate one time hardware calibration .

34.6.15 DDR PHY

The DDR PHY encapsulates all functionality required to interface to external DDR DRAM devices into a single module. This module is used to control the off-chip data capture and synchronization logic for the read data. This module performs the following functions:

- Contains all data registers used to launch data, address, and control signals to the DDR memory and the memory controller.
- Controls the off-chip data capture and synchronization logic for the read data.
- Includes DLL for timing.

34.6.15.1 High Level Block Diagram

DRAM MC uses a slice-based approach for the DDR PHY. Each slice manages a byte (8 bits) of data and its corresponding DQS and DM signals.

A high level block diagram of the PHY is provided in Figure 34-197.

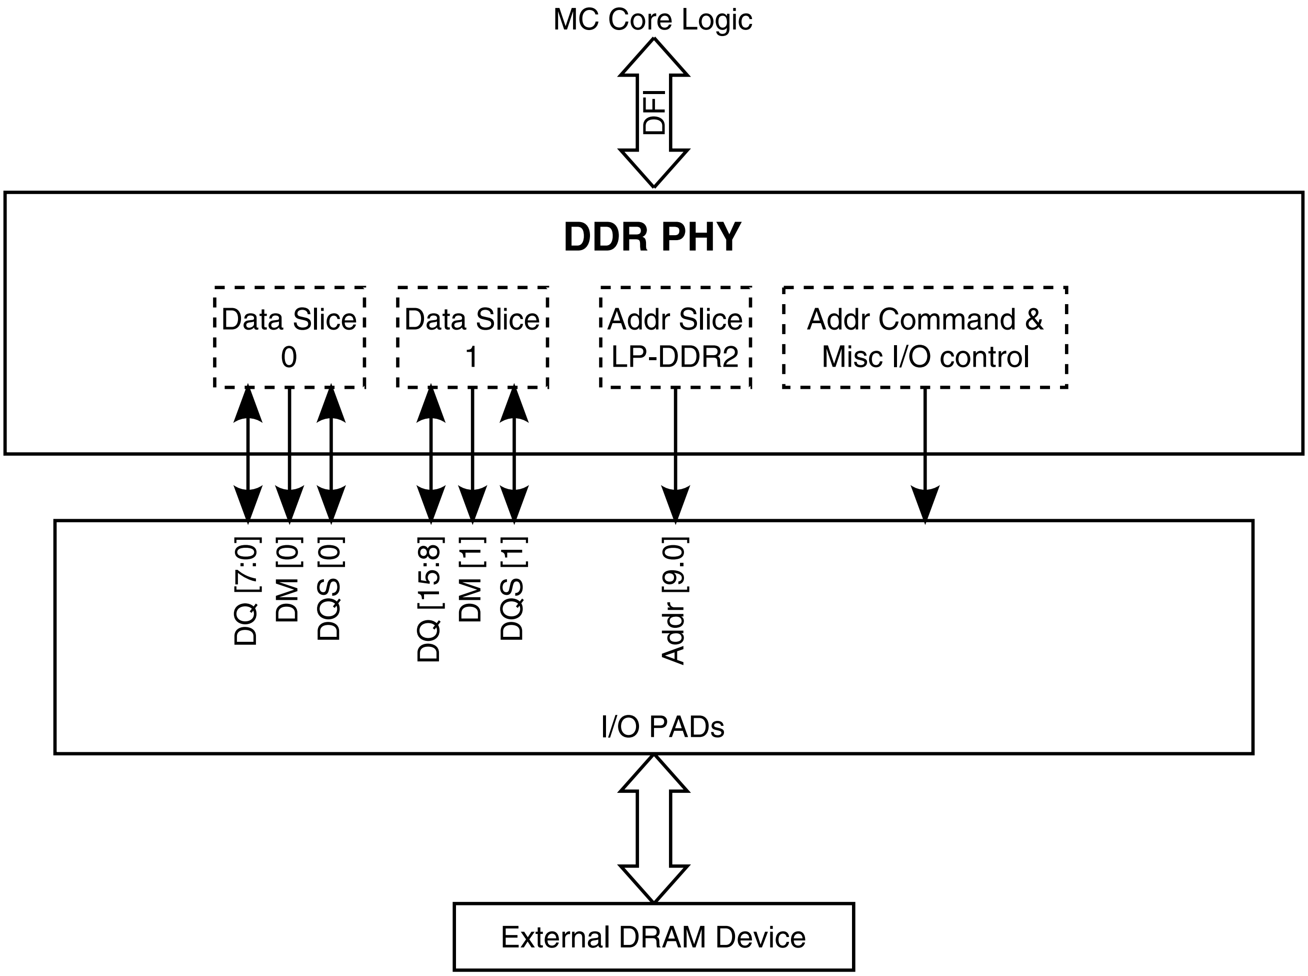

Figure 34-197. DDR PHY High Level Block Diagram

34.6.15.2 DFI

The interface between the DRAM MC core logic and the DDR_PHY is called "DFI". The "D" stands for "DRAM Controller" while "FI" is a reference to "PHY".

34.6.15.3 The I/O Timing of Address & Command

Figure 34-198 illustrates the I/O timing of Address and Command.

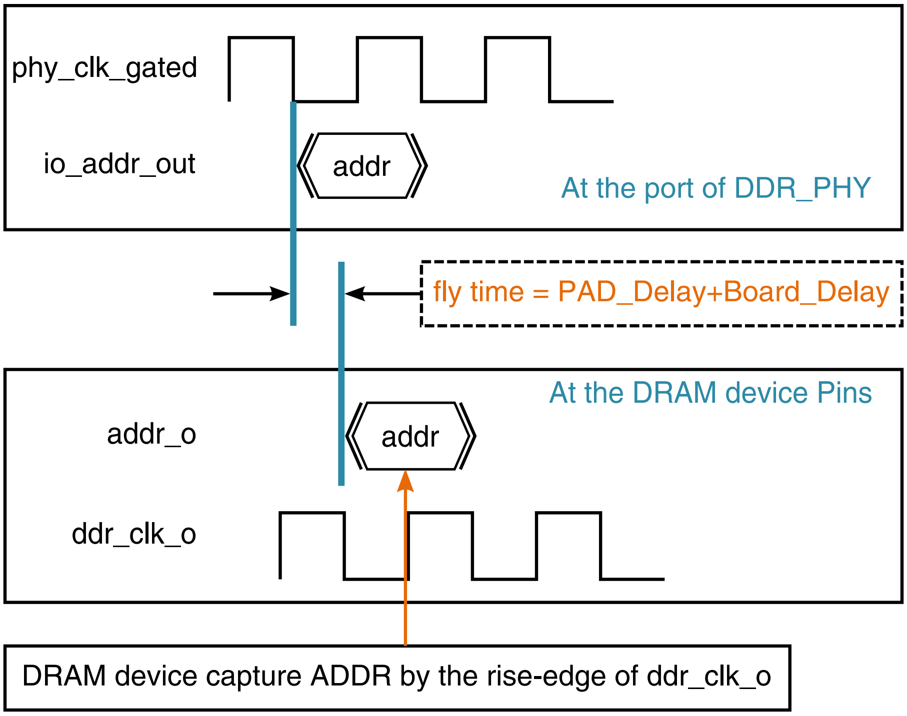

Figure 34-198. The I/O Timing of Address

The address & command signals including all DRAM interface signals except the DQ & DQS: clock-enable (CKE), chip-select, bank-address, row/cloumn_address, CASn, RASn, WEn, etc.

1. The Address & command signals is latched out by the fall-edge of PHY_CLK; In another word, the rise-edge of PHY_CLK is center-aligned with the output Address & Command signals.
2. The "fly-time" means the signals propagation time start from the DDR_PHY logic, go accross the output I/O (PAD), go through the signal trace on the board, then arrive the PIN of the DRAM device.
3. The DRAM device would capture the Address & Command signals by the rise edge of ddr_clk_o.
4. Figure 34-198 illustrates the address timing for DDR3. The timing of LPDDR2 is quite different.

34.6.15.4 The Address Timing of LPDDR2

There's a special slice "Addr Slice", illustrated in Figure 34-197. It is designed to deal with the address[9:0] of LPDDR2 device which require double-data-rate timing. Either the address[9:0] (in LPDDR2 mode) or the DDR write data timing can be illustrated by Figure 34-202.

34.6.15.5 Data Slice Overview

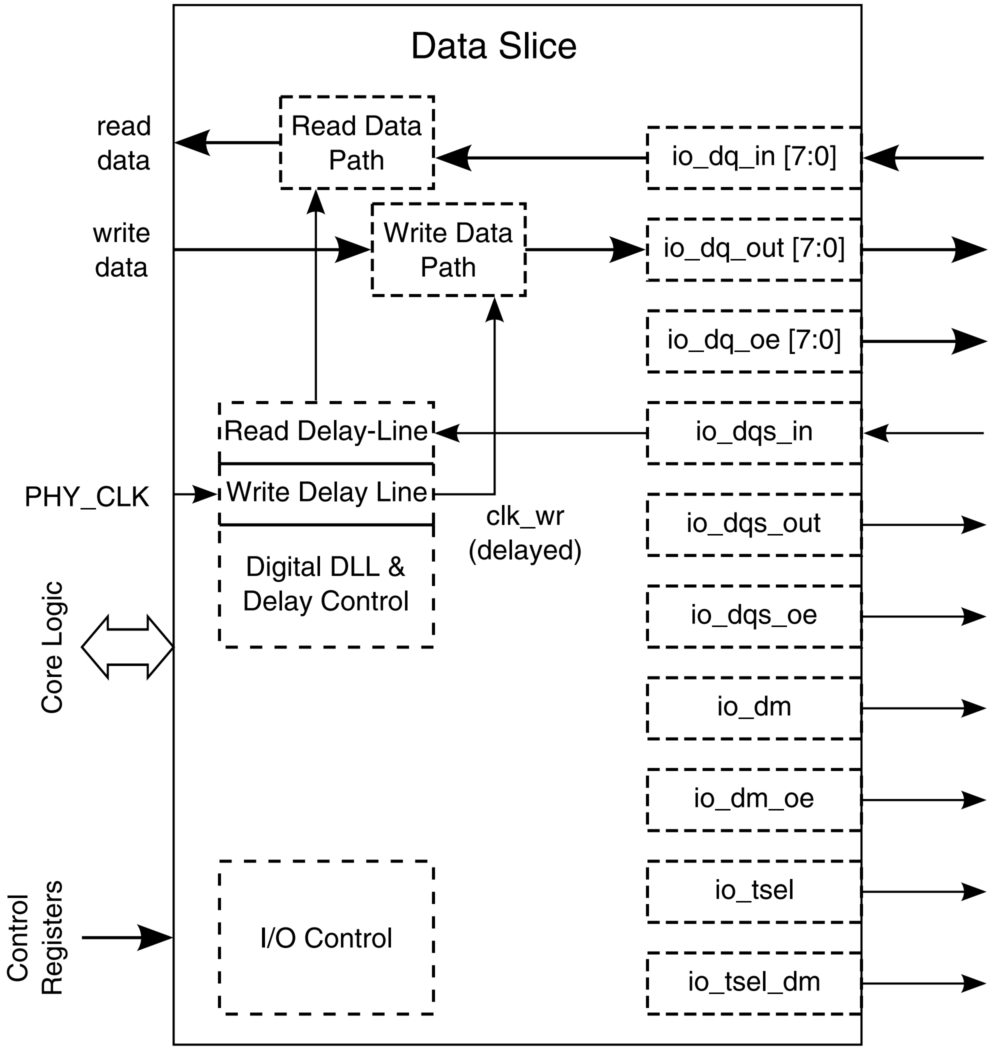

Figure 34-199. DDR PHY Data Slice

Each data-slice manages a byte (8-bit) of data and its corresponding signals.

The "Read Data Path" capture read data by latching it into read data buffers by both the posedge & negedge of "delayed_dqs". Then, the read data is synchronized from "delayed_dqs" clock domain to PHY_CLK domain.

The "Write Data Path" synchronize write data and write data mask (the "dm") from PHY_CLK domain to "dqs_out" domain.

The "Digital DLL" controls the delay values of "read delay-line" and "write delay-line". It can be bypassed and switched to manual delay control mode. In manual delay control mode, the delay values of read/write delay-line can be programmed into it's control registers separately.

34.6.15.6 Read Data Capture

When reading, DDR (dual data rate) devices send a data strobe (DQS) signal coincident with the read data. The edges of this DQS strobe are aligned (edge-aligned) with the data output by the DDR devices.

To latch read data into DRAM MC read data buffer, it requires that the latch clock edge is center-aligned with the data. Thus, a delayed version of the DQS strobe signal must be used to capture the data. Because the frequency of the DQS strobe signal is matched to the PHY_CLK, the delay is a relative number based on the period of the PHY_CLK. In the example shown in Figure 34-200, the delay is set to approximately 25% of the PHY_CLK cycle.

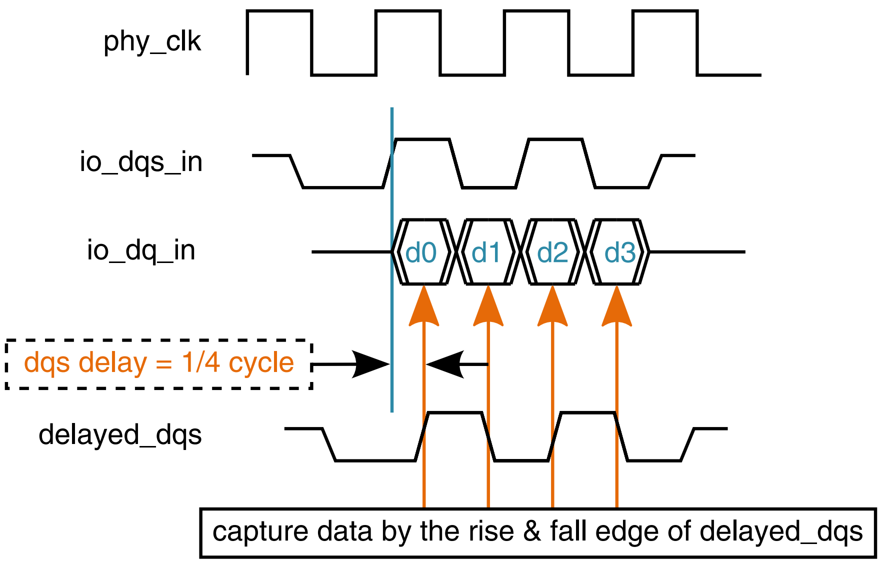

Figure 34-200. Read Data Capture

34.6.15.7 Synchronize Read Data From delayed_dqs To PHY_CLK domain

Read data is captured into data buffers by the "delayed_dqs". It must be synchronized into PHY_CLK domain, then returned to DRAM MC core logic.

Figure 34-201 illustrates how the read data from the external DRAM device is captured and synchronized to DRAM MC core logic.

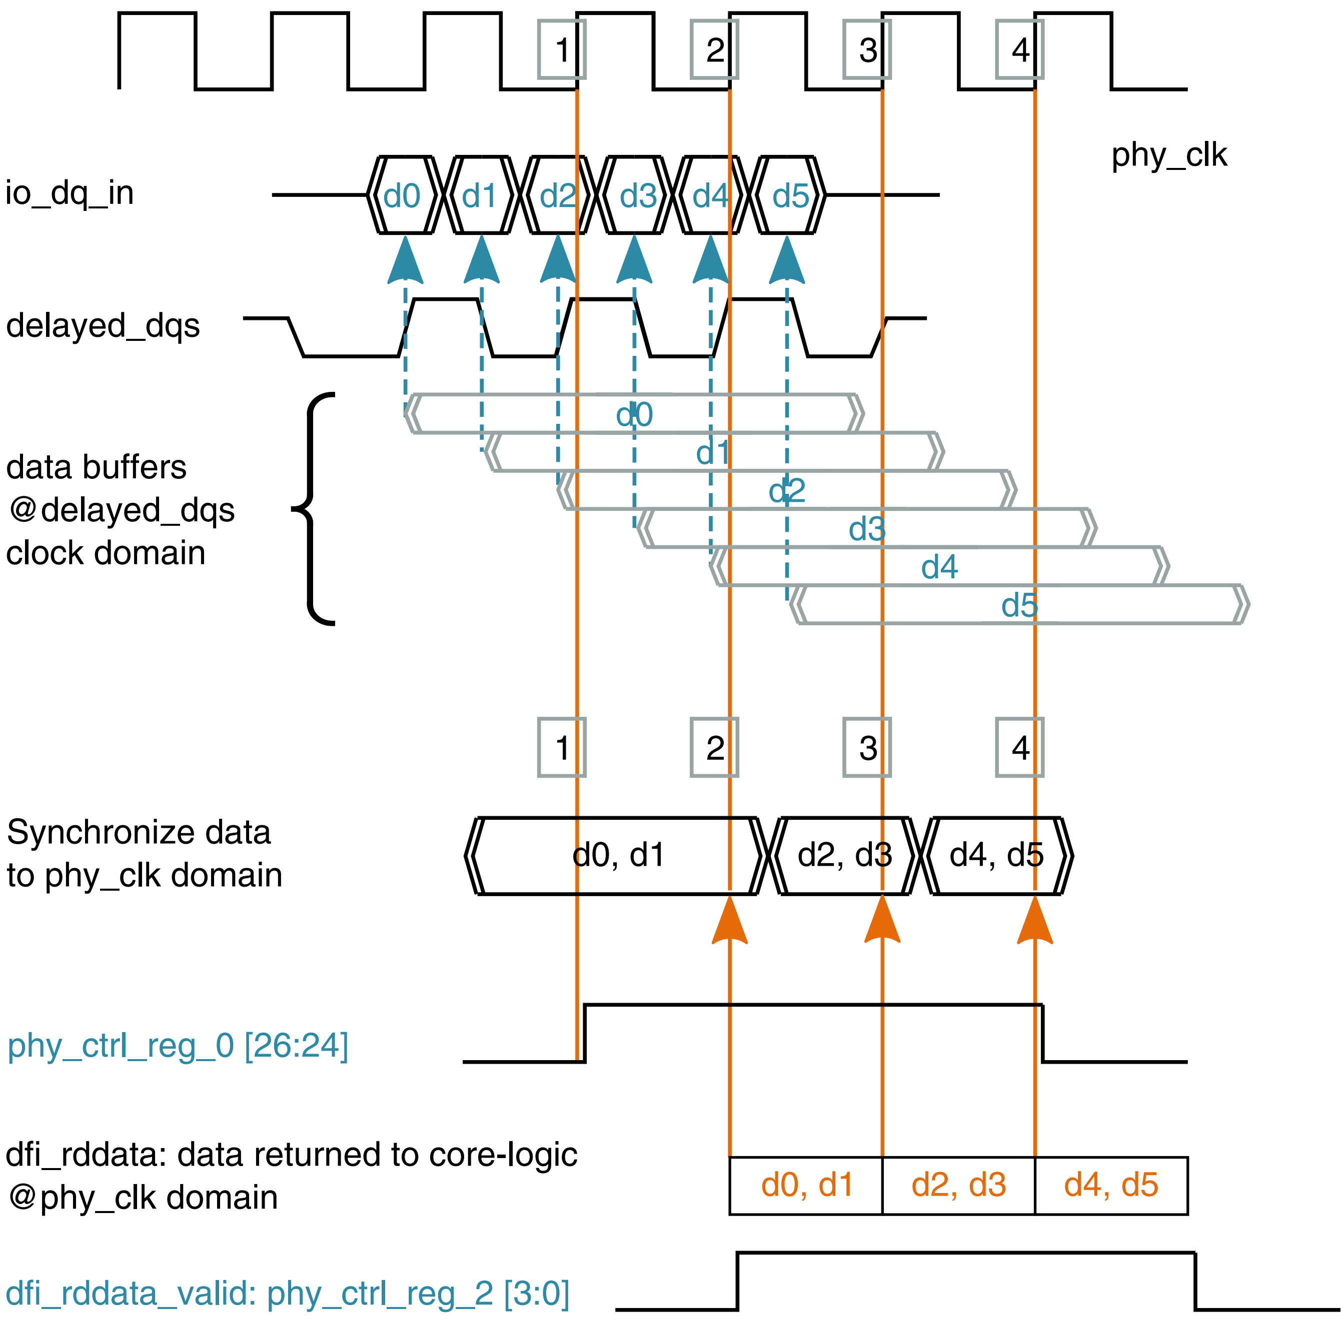

Figure 34-201. Synchronize Read Data

1. io_dq_in & io_dqs_in are not aligned with PHY_CLK in phase. Many factors affect the phase of io_dq/dqs_in, such as voltage, temperature, board layout, manufacture process, and so on.

2. Must capture the io_dq_in by delayed_dqs to meet the critical timing requirement in high frequency.
3. The data path width @PHY_CLK domain is twice of the data path width @delayed_dqs domain.
4. The DRAM MC core logic fetch read data by the rise-edge of PHY_CLK. The DRAM MC core logic fetch read data by two important signals: dfi_rddata & dfi_rddata_valid.
5. The user can program the timing position of "dfi_rddata & dfi_rddata_valid" by programmable registers "phy_ctrl_reg_0[26:24]" & "phy_ctrl_reg_2[3:0]". The unit is one cycle of PHY_CLK.
6. In this example, read data "d0,d1" getting valid before edge number "1" of PHY_CLK and is synchronized at edge "2" of PHY_CLK. Both the setup & hold time requirement are met which means read data could be fetched by core logic safely. Alternatively, read data can also be returned to core logic at edge number "1" of PHY_CLK, a cycle prior to the example. In this scenario, need to set the value of register "phy_ctrl_reg_0[26:24]" & "phy_ctrl_reg_2[3:0]" one number less. The, the "dfi_rddata" & "dfi_rddata_valid" would getting valid one cycle earlier. The benefit is that the read latency was shorten by one cycle, it help increasing the system performance. But, there's a timing risk on the "setup time", if the io_dq/dqs_in comes a little late, "setup time violation" may occur and the un-expected data would be returned to core logic, and, might lead to system crash.

34.6.15.8 Write Data Path

Figure 34-202 illustrates the write data path.

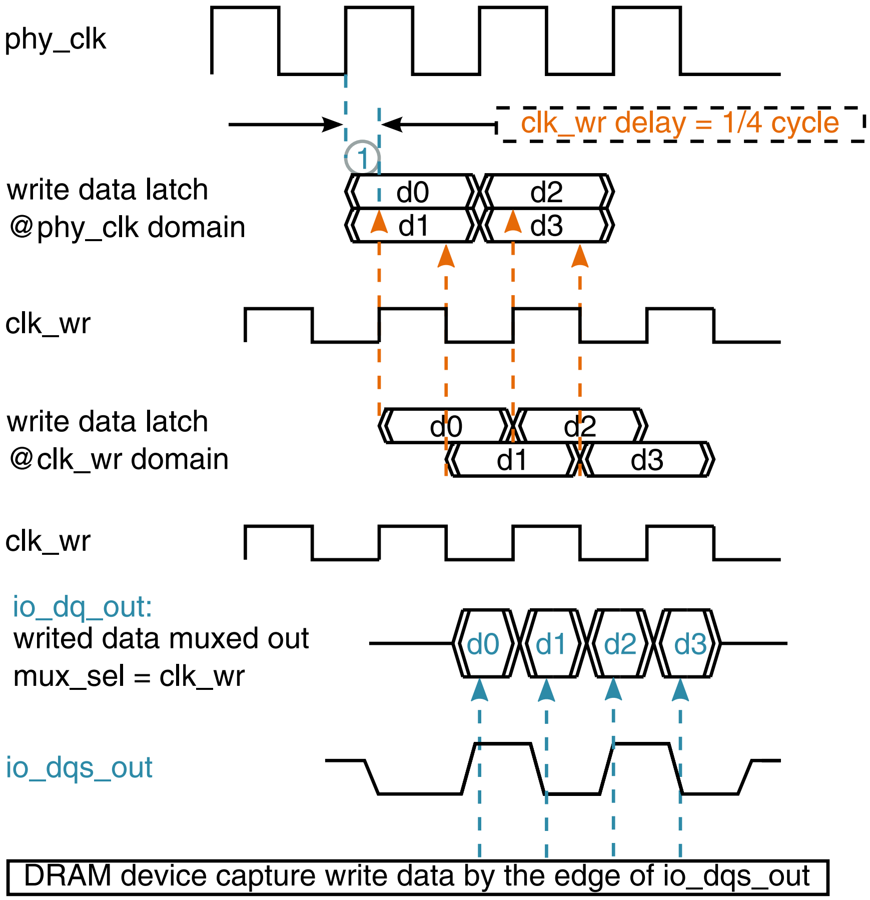

Figure 34-202. Write Data Path

NOTE

The marker "1" indicates that the "setup time" here for data "d0" is only "1/4 cycle", that would be critical in timing. The Low-Latency Option of Write Data Path , contains more detail on it.

The "io_dqs_out" and the PHY_CLK are edge-aligned in this DRAM MC design. This helps to meet the "tDQSS" timing requirement defined by the DRAM device.

The "io_dqs_out" and the "io_dq_out" are center-aligned, as required by the DRAM device.

34.6.15.8.1 The Low-Latency Option of Write Data Path

DDR_PHY provides 2 write data path options for the user :

1. The "Standard-Latency" option.

An extra latch at PHY_CLK domain is asserted into the write data path, right ahead of the latch at clk_wr domain (at the place of marker "1" in Figure 34-202). By this means, the asserted-latch and the latch@clk_wr are put back-to-back. The total delay in write data path is "1+1/4" cycle. It is safe in timing but decrease the performance by adding one cycle latency.

2. The "Low-Latency" option.

   The asserted latch for standard-latency is bypassed. The total delay in write data path is "1/4" cycle. There's risk in timing of write data path but it has higher performance than standard-latency case.

34.6.15.9 Digital DLL and the Delay-Line

Due to the asynchronous nature of the DRAM devices, the timing requirements for capturing and receiving data between the MC and the DRAM devices must be addressed. This DRAM MC contains a circuit that, in conjunction with I/O cell circuitry, can be used to meet the timing requirements for DRAM devices. The delay compensation circuit was designed with the following features:

- Programmable read strobe delay specified as a percentage of a clock cycle.
- Programmable write data delays specified as percentages of a clock cycle.
- Delay compensation circuit re-sync circuitry activated during refresh cycles to compensate for temperature and voltage drift.
- Separate delay chains for each read DQS signal from the DRAM devices.

The delay compensation circuitry relies on a master/slave approach. There is a master delay line which is used to determine how many delay elements constitute a complete cycle. This count is used, along with the programmable fractional delay settings, to determine the actual number of delay elements to program into the slave delay lines. The master and slave delay lines are identical. This approach allows the memory controller to observe a clock and then delay other signals a fixed percentage of that clock. The DLL logic does not actively generate clock signals.

The actual delay element for the delay lines is user-selectable.

Figure 34-203 shows the block diagram for a digital DLL.

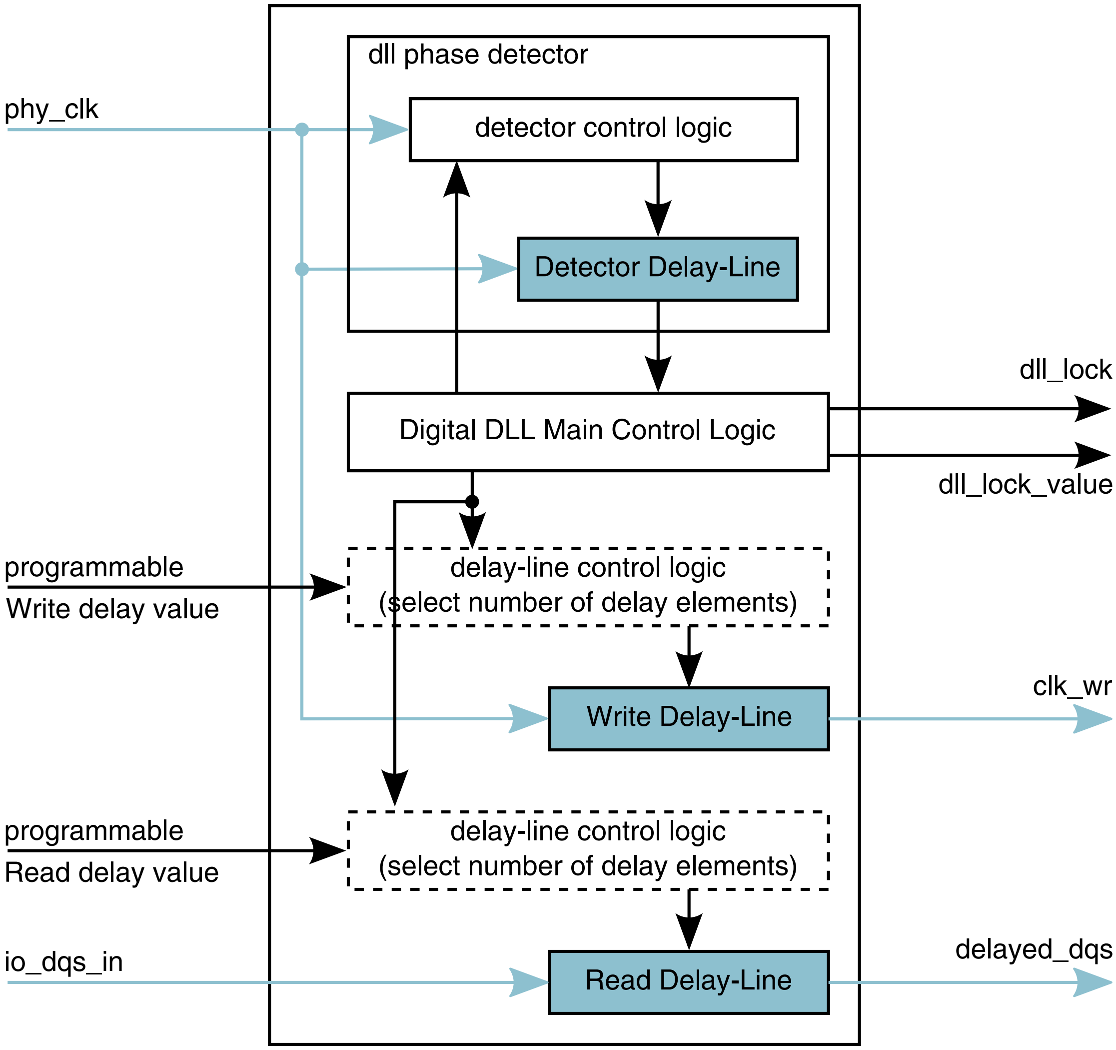

Figure 34-203. Digital DLL

The delay-line is comprised by 255 tiny delay-elements. The delay value of each delay element are almost the same. And the number of delay elements which is in use to form a delay result is configurable.

There are two modes for the delay-line control :

1. Auto-configure mode:

   This process begins by the "phase-detector". Once the phase-detector successfully complete the detection, it will raise the "dll_lock" signal and output "dll_lock_value" which indicates the delay of cone cycle. The number of elements that are needed to capture an entire clock cycle is then converted into an unsigned integer named encoder [7:0]. This integer is used as the dividend for the read and write delay parameters. The actual delay setting for the delay lines is calculated by multiplying

the encoder [7:0] integer by the parameter settings for each delay line and then dividing by 128 and rounding. These values are then encoded into a one-hot counter and updated at initialization and at every refresh interval.

2. Bypass mode, or manual configure mode:

   The phase detector can be bypassed. The number of delay elements for read & write delay line is programmed manually.

NOTE

In case the number of delay elements is fixed, the actual delay value (in nanoseconds) of a delay-line would change according to environmental conditions such as voltage, temperature, etc.

Using the auto-configure mode helps to eliminate the change of delay value because the reference delay itself also changes along with environmental conditions.

34.6.15.10 Configure the "output enable" of I/O Control

Some DRAM MC I/Os require a control signal named "output enable". Only when the "output enable" signal is active, the I/O can drive signals out, refer to Figure 34-204.

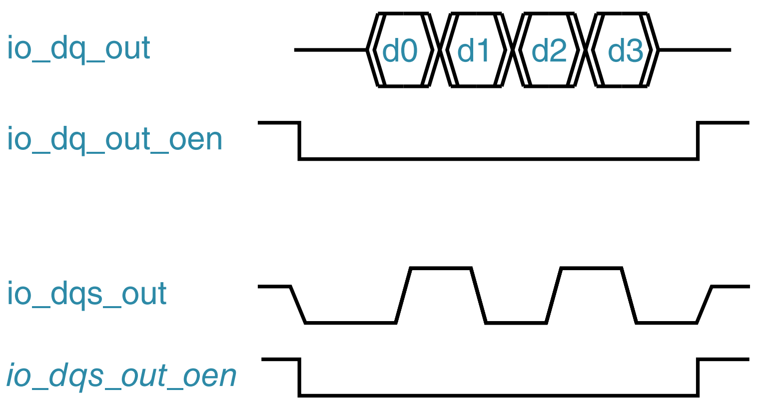

Figure 34-204. Output Enable of DRAM MC i/Os

There are 3 kinds of output enable signals in this DRAM MC design:

- io_dq_out_oen

  output enable for write data.

- io_dqm_oen

output enable for write data mask. Please configure it exactly the same as io_dq_out_oen.

- io_dqs_oen

  output enable for write data strobe.

The suffix "_oen" means the output enable signal is active low. The start time and the end time of a output enable signal can be configured separately. The start time and the end time can be adusted by 1/4 clock cycle in unit.

To meet the timing requirement of the I/O circuits, the start time of each output enable must be prior to it's corresponding output signal, and, the end time must be later than it's corresponding signal. In another word, the output enable signal must be "wider" than the output signal. The margin at start time is named "pre-amble" and the margin at end time is named "post-amble". In the example of Figure 34-204, pre-amble = 1/2 cycle while post-amble = 1/4 cycle.

34.6.16 Levelling Operations through Software

DDR3 memories feature leveling capabilities that allow more accurate alignment of critical timing signals for read and write operations. DDR3 PHYs must account for the delays induced by the fly-by topology to properly align the write DQS with the memory clock at the memory interface and to properly time the gate signal for read data capture. There are three different leveling delays which may be tuned in the DDRMC in DDR3 mode:

- Write leveling: Used to locate the delay at which the write DQS rising edge aligns with the rising edge of the memory clock.
- Gate training: Used to correctly time the opening of the gate for the read DQS.
- Read leveling: Used to center the read DQS in the DQ data eye on a memory read. This process assumes that gate training has been completed.

The DDRMC supports all of the leveling operation modes through software. Software write leveling refers to a mode of operation where software must handle the leveling sequences including setup.

34.6.16.1 Detailed Software Leveling Procedure

Leveling operations should be performed after memory initialization. In addition, a leveling operation may be initiated by software at any point, or as a response to a hardware interrupt.The DDRMC will inform the user interface of a leveling request by

hardware through the leveling request interrupt CR80[INT_STAT]. This bit is tied to the CR94[LVL_STAT], which contains a single bit per type of leveling operation and is set whenever a leveling request is sent from the PHY, if the periodic refresh timers for a leveling request are triggered, or if the request parameter is set.

Software is not required to use the CR94[LVL_STAT] or respond to a hardware interrupt for leveling requests. However, if the user wishes to count refreshes between leveling operations, then this bit will inform the user when the refresh counter expires. If desired, software may respond to a leveling interrupt by reading the CR94[LVL_STAT] and then programming the CR93[SW_LVL_MODE] with the type of leveling procedure requested. If the interrupt and lvl_status bit are not being used, software must program the CR93[SW_LVL_MODE] with the operation being implemented. The encoding of the 2-bit CR93[SW_LVL_MODE] is:

- ’b00: No leveling
- ’b01: Write leveling
- ’b10: Read leveling
- ’b11: Gate training

After specifying the type of leveling, the software algorithm should initiate the procedure by setting the CR90[SWLVL_START]to ’b1. This triggers the memory controller (MC) to complete any commands in progress, inhibit the command queue from accepting additional requests, and issue a precharge_all command to the memory to close all banks (if necessary). The memory controller will then issue the appropriate mode register commands to place the memories into write leveling mode or to enable read leveling through the MPR register. After meeting any applicable timing parameters, the MC will also assert one of the DFI leveling enable signals which enables the appropriate logic in the PHY.

The CR94[SWLVL_OP_DONE] is used to inform the software of the status of any active operations. This parameter will be cleared to ’b0 during any initialization, load or exit operation is being performed and set to ’b1 when the operation is complete. The leveling operation complete interrupt (bit 18) will also be set to ’b1 in the CR80[INT_STAT] when the CR94[SWLVL_OP_DONE] is set. The software may wait for the interrupt or monitor this parameter to indicate that the operation in process has completed, and another action may be performed. The interrupt may be disabled by setting the associated bit in the CR82[INT_MASK] to ’b1 if it is preferable not to have the interrupt firing.

The procedures for write and read leveling are influenced by the type of write leveling, gate training and read leveling support provided by the PHY and defined through the MC input signals.The procedures described in this document are only applicable for the MC Evaluation mode.

If the PHY is operating in MC Evaluation mode, after initialization, the appropriate delay parameters should be written with the value of delay that is needed for each data slice X in the PHY. The delay parameters used by the software leveling option are:

- Write Leveling: WRLVL_DLL_X bits
- Gate Training: RDLVL_GTDL_X bits
- Read Leveling: WRLVL_DL_X bits

At this point, the software should set the CR93[SWLVL_LOAD] to ’b1. This action will trigger the MC to de-assert the CR94[SWLVL_OP_DONE]and the MC will initiate a loading of the delay values into the data slices. The MC will then wait for the load operation to complete, and initiate a write level strobe or a read burst. The MC will wait for the response from the memory and save the response into the CR94[SWLVL_RESP_2], CR95[SWLVL_RESP_1],CR94[SWLVL_RESP_0] for each slice X. Once all responses are saved, the MC will assert the CR94[SWLVL_OP_DONE] and generate an interrupt. This informs the user that the response data is available for the initial delay values.

The software should use the response values CR94[SWLVL_RESP_2], CR95[SWLVL_RESP_1],CR94[SWLVL_RESP_0] to determine the next operation. For MC Evaluation mode, the response will indicate if the delay is appropriate, or must be increased or decreased. If the delay must be changed, the new delay value should be written to the associated parameter and the load sequence should be performed again.

If the delays are accurate (MC Evaluation mode), the software should now exit leveling by setting the CR94[SWLVL_EXIT] to ’b1. This triggers the MC to clear the mode registers in the memories,de-assert the DFI leveling enable signal and enable the command queue for normal operation. The software is not required to complete the entire procedure prior to exiting. The user may exit after initialization or after a load operation, even if the response does not indicate completion or accurate values. Any writes to the CR94[SWLVL_EXIT] while the CR94[SWLVL_OP_DONE] is clear will be ignored. As with other operations, the CR94[SWLVL_OP_DONE] will be de-asserted at the start of the exiting process and asserted with an interrupt generation when exit has completed.

The value in the CR93[SW_LVL_MODE] is sampled when the CR93[SWLVL_START] is asserted, and must remain at the same value until the CR94[SWLVL_EXIT] operation has been completed. If this parameter is changed during any load operations, the MC may exhibit unstable behavior.

The software leveling logic may be used to level any chip select in the system. The user may identify a particular chip select by programming the CR95[WRLVL_CS] (for write leveling) or CR101[RDLVL_CS] (for gate training or read leveling). If there are multiple chip selects in the system that must be leveled, the entire leveling procedure must be completed for one chip, then the CR95[WRLVL_CS] or CR101[RDLVL_CS] should be changed and the entire leveling procedure performed again. Only one set of delays may

be stored in the DDRMC. The DDRMC does not contain storage for the delays for multiple chip selects. If this is required for leveling, the PHY must also contain the register space to store those delay values.

NOTE

Although an interrupt is generated at the end of each step in the leveling process, the system does not have access to the memory served by the controller. The command queue is disabled during this time and the memory is in a state in which it will not accept read or write commands. Any interrupt-servicing routine will need to be developed with the knowledge that it will not have access to this memory, or the user may first mask interrupt(s) by setting the associated bits in the CR82[INT_MASK] to ’b1 before performing leveling through software.

34.6.16.2 Software Write Leveling

Write leveling is a feature of DDR3 memories that is used to align the rising edge of the memory clock and the rising edge of the write data strobe relative to each other at the memory interface, accounting for system skew. Write leveling must be done per data slice to allow proper alignment of clock and DQS.

The procedure outlined in the abovementioned Detailed Software Leveling Procedure Detailed section will be followed for write leveling, gate training and read leveling. This section details the specific procedure for write leveling through software.

Several parameters in the Controller must be set to appropriate values prior to initiating a software write leveling operation. The CR96[WRLVL_EN] must be cleared to ’b0 to disable hardware write leveling and the CR95[WRLVL_CS] must be programmed with the rank of memory to be leveled. The CR93[SW_LVL_MODE] must also be programmed to ’b01 to indicate the desire to perform a write leveling operation through software.

34.6.16.2.1 Software Write Leveling in MC Evaluation Mode

If the system is relying on the MC to evaluate the responses and set the delay values, the software should perform the following sequence:

1. Software may initiate a write leveling operation at any time, or as a response to the leveling request interrupt (bit 17) being set to ’b1 in the CR80[INT_STAT]. Software is not required to respond to the hardware interrupt.

If the hardware interrupt is being used, the refresh timer may be have expired. Read the lvl_status parameter to determine the type of leveling operation being requested. If bit [0] is set, then a write leveling operation is being requested.

2. Ensure that appropriate values are programmed in the CR139[PHY_WRLV_DLL], CR139[PHY_WRLV_EN], CR139[PHY_WRLV_LOAD], CR141[PHY_WRLV_RESP], CR139[PHY_WRLV_RESPLAT], CR140[PHY_WRLV_WW], CR17[TMOD], CR96[WLDQSEN], CR96[WLMRD].
3. Program the CR95[WRLVL_CS] for write leveling.
4. Program the CR93[SW_LVL_MODE] to ’b01.
5. Set the CR93[SWLVL_START] to ’b1.

   The MC will clear the CR94[SWLVL_OP_DONE], complete the current command, inhibit the command queue and issue a precharge_all to the memory banks if necessary. A mode register write will place the memory (identified by the CR95[WRLVL_CS] into write leveling mode and, wait TMOD cycles, the PHY write level enable signal will be asserted to enable the PHY write leveling logic. After WLDQSEN cycles, the DQS strobe is sent.

6. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.
7. Program delay values for each data slice X into the WRLVL_DLL_X bits.
8. Set the CR93[SWLVL_LOAD] to ’b1.

   The MC will clear the CR94[SWLVL_OP_DONE], wait PHY write level enable signal and then load the delay values onto the PHY write level gate delay signals. After PHY write level load cycles, the PHY write level load signal will be asserted. The MC will ensure that PHY write level DLL has elapsed and then initiate a write level strobe. At PHY clocks after a write command cycles, the MC will load the responses from the PHY_WRLVL_RESP signals into the SWLVL_RESP_X bits for each data slice X.

9. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.
10. Read the responses from the SWLVL_RESP_X bits.

    A “1” indicates the rising edge of the strobe occurred during the high phase of the clock and a “0” indicates the rising edge of the strobe occurred during the low phase of the clock. In general, the user will want to increase the delay if a “0” response was received or decrease the delay if a “1” response was received.

11. Based on the response for each slice, a higher or lower delay value should be programmed into each WRLVL_DLL_X bits. Note that the software must track the “previous” value of the response for future evaluation
12. Set the CR93[SWLVL_LOAD] to ’b1.

The MC will clear the CR94[SWLVL_OP_DONE], load the updated delay values onto the PHY write level delay signals, wait PHY write level load and then assert the PHY write level load signal. The MC will wait PHY write level DLL cycles and ensure that PHY WRVL_RR has elapsed before issuing another write level strobe. After PHY WRLV_RESP cycles, the MC will load the responses from the WRLV_RESP signals into the SWLVL_RESP_X bits for each data slice X.

13. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt CR80[INT_STAT] until the operation has completed
14. Read the responses from the SWLVL_RESP_X bits. The meaning of the response is based on the previous response and how the delay was changed for this iteration.
15. Repeat steps 11 through 14 until the transition point has been located, or the delay value has reached the maximum or minimum possible.
16. Set the CR94[SWLVL_EXIT] to ’b1.

    The MC will clear the CR94[SWLVL_OP_DONE] , perform a mode register write to disable the read leveling mode for the memory and de-assert the PHY write level enable signal. The command queue will be enabled for normal operation.

17. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.

Table 34-218. Write Leveling Responses in MC Evaluation Mode

Previous	Current	Delay Change	Suggested Action
0	0	Incremented	Increment delay value
0	0	Decremented	Decrement delay value
0	1	Incremented	Rising edge transition point has been located.
0	1	Decremented	Decrement delay value (leveling is attempting to locate rising edge.)
1	0	Incremented	Increment delay value (leveling is attempting to locate rising edge.)
1	0	Decremented	Rising edge transition point has been located.
1	1	Incremented	Increment delay value
1	1	Decremented	Decrement delay value

34.6.16.2.2 Software Write Leveling Software Considerations

There are certain cases that the software should be prepared to consider for write leveling:

1. The delay value may reach the minimum or maximum possible without finding the edges of the clock relative to the strobe. In this case, the software should determine whether the smallest or largest value of the delay line is most appropriate, or whether another adjustment is required to place the signal within the range of the delay line.
2. If the initial delay value causes the strobe to just miss the rising edge of the clock, a full cycle of delay may be required to find the next rising edge. However, this full cycle of delay may cause the data to ultimately be delayed a cycle longer than needed. If the initial strobe just misses the clock edge, the initial value may be the correct value of delay. For example, if the initial delay tested responded with a “1”, then the correct delay may be 0x0.
3. The software must be aware of any limitations of the delay lines in the PHY, including maximum delay values that can be programmed.
4. Once the data slices have been leveled, incremental re-leveling may be accomplished more quickly by starting with the previous value and incrementing or decrementing the delay based on the responses.
5. Ideally, the signal should be placed away from the edges of the delay line to allow flexibility in adjustment.

34.6.16.3 Software Gate Training

Gate training is a feature of DDR3 memories that is used to align the rising edge of the read data strobe gate in the middle of the preamble of the read data strobe signal at the memory interface. The procedure outlined in abovementioned Detailed Software Leveling Procedure section will be followed for write leveling, gate training and read leveling. This section details the specific procedure for gate training through software.

Several parameters in the Controller must be programmed to appropriate values prior to initiating a software gate training operation. The CR149[RDLVL_GATE_EN]must be cleared to ’b0 to disable hardware gate training and the CR101[RDLVL_CS] must be programmed with the rank of memory to be leveled.

Since the gate is being aligned to the first read DQS, the user should adjust the gate by a 1/2 cycle forward prior to performing gate training. Then, the 1/2 cycle delay should be removed, aligning the gate in the center of the preamble. In addition, the DFI specification requires that the gate signals must assert during the preamble or first high phase of the read DQS.

The DFI training interface timing parameters must be defined for the system. The CR93[SW_LVL_MODE] must also be set to ’b11 to indicate the desire to perform a gate training operation through software.

34.6.16.3.1 Software Gate Training in MC Evaluation Mode

The software should perform the following sequence:

1. Software may initiate a write leveling operation at any time, or as a response to the leveling request interrupt (bit 17) being set to ’b1 in the CR80[INT_STAT]. Software is not required to respond to the hardware interrupt.

   If the hardware interrupt is being used, the refresh timer may be have expired. Read the CR90[LVL_STATUS] parameter to determine the type of leveling operation being requested. If bit [0] is set, then a write leveling operation is being requested.

2. Ensure that appropriate values are programmed in the CR144[PHY_RDRLV_DLL], CR144[PHY_RDLV_EN], CR144[PHY_RDLV_LOAD], CR144[PHY_RDLV_RES], CR146[PHY_RDLV_RESP], CR145[PHY_RDLV_RR].
3. Program the CR101[RDLVL_CS] with the target chip select for gate training.
4. Program the CR93[SW_LVL_MODE] to ’b01.
5. Set the CR93[SW_LVL_MODE] to ’b11.
6. Set the CR93[SWLVL_START] to ’b1.

   The MC will clear the CR94[SWLVL_OP_DONE], complete the current command, inhibit the command queue and issue a precharge_all to the memory banks if necessary. An MPR write will enable read leveling for the memory (identified by the CR101[RDLVL_CS) and the PHY read level gate enable signal will be asserted to enable the PHY gate training logic.

7. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.
8. Program delay values for each data slice X into the RDLVL_GTDL_X bits.
9. Set the CR93[SWLVL_LOAD] to ’b1.

   The MC will clear the CR94[SWLVL_OP_DONE], wait PHY read level enable signal and then load the delay values onto the PHY read level gate delay signals. After PHY read level load cycles, the PHY read level load signal will be asserted. The MC will ensure that PHY read level DLL has elapsed and then initiate a read burst. At PHY clocks after a read command cycles, the MC will load the responses from the PHY_RDLVL_RESP signals into the SWLVL_RESP_X bits for each data slice X.

10. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.

    The value returned will be the sampled value of DQS at the rising edge of the gate signal. In general, the user will want to increase the delay if a “0” response was received or decrease the delay if a “1” response was received.

11. Based on the response for each slice, a higher or lower delay value should be programmed into each RDLVL_GTDL_X bits. Note that the software must track the "previous" value of the response for future evaluation.
12. Set the CR93[SWLVL_LOAD] to 'b1. The MC will clear the CR94[SWLVL_OP_DONE], load the updated delay values onto the PHY RDLVL_GTDL_X signals, wait PHY read level load and then assert the PHY read level load signal. The MC will wait PHY read level DLL cycles and ensure that PHY RDVL_RR has elapsed before issuing another read burst. After PHY RDLVL_RESP cycles, the MC will load the responses from the RDLVL_RESP signals into the SWLVL_RESP_X bits for each data slice X.
13. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt CR80[INT_STAT] until the operation has completed.
14. Read the responses from the SWLVL_RESP_X bits. The meaning of the response is based on the previous response and how the delay was changed for this iteration.
15. Repeat steps 11 through 14 until the gate is aligned to the rising edge of the read DQS for each data slice, or the delay value has reached the maximum or minimum possible
16. Set the CR94[SWLVL_EXIT] to 'b1.

    The MC will clear the CR94[SWLVL_OP_DONE] , perform a mode register write to disable the read leveling mode for the memory and de-assert the PHY read level gate enable signal. The command queue will be enabled for normal operation.

17. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.

Table 34-219. Gate Training Responses in MC Evaluation Mode

Previous	Current	Delay Change	Suggested Action
0	0	Incremented	Increment delay value
0	0	Decremented	Decrement delay value
0	1	Incremented	Rising edge transition point has been located.
0	1	Decremented	Decrement delay value
1	0	Incremented	Increment delay value
1	0	Decremented	Rising edge transition point has been located.
1	1	Incremented	Increment delay value
1	1	Decremented	Decrement delay value

34.6.16.3.2 Software Gate Training Software Considerations

There are certain cases that the software should be prepared to consider for write leveling:

1. If the delay value reaches the minimum or maximum possible without finding the edge of the DQS, an error has occurred in gate training.
2. Once the data slices have been leveled, incremental re-leveling may be accomplished more quickly by starting with the previous value and incrementing or decrementing the delay based on the responses.
3. Once gate training has been completed, the user should use read and write data patterns to verify that the gate was placed correctly within the preamble.
4. Ideally, the signal should be placed away from the edges of the delay line to allow flexibility in adjustment.

34.6.16.4 Software Read Leveling

Read leveling training is a feature of DDR3 memories that is used to align the rising edge of the read data strobe in the middle of the data eye at the memory interface. The procedure outlined in Software Leveling Procedure Detailed section, will be followed for write leveling, gate training and read leveling. This section details the specific procedure for read leveling through software.

Several parameters in the Controller must be programmed to appropriate values prior to initiating a software read leveling operation. The CR148[RDLVL_EN] must be cleared to ’b0 to disable hardware read leveling and the CR101[RDLVL_CS] must be programmed with the rank of memory to be leveled. The leveling edge must be identified in the CR101[RDLVL_EDGE]. The DFI training interface timing parameters must be defined for the system. The CR93[SW_LEVELING_MODE] must also be programmed to ’b10 to indicate the desire to perform a read leveling operation through software.

34.6.16.4.1 Software Read Leveling in MC Evaluation Mode

The software should perform the following sequence:

1. Software may initiate a write leveling operation at any time, or as a response to the leveling request interrupt (bit 17) being set to ’b1 in the CR80[INT_STAT]. Software is not required to respond to the hardware interrupt.

   If the hardware interrupt is being used, the refresh timer may be have expired. Read the CR90[LVL_STATUS] parameter to determine the type of leveling operation being requested. If bit [0] is set, then a write leveling operation is being requested.

2. Ensure that appropriate values are programmed in the CR144[PHY_RDRLV_DLL], CR144[PHY_RDLV_EN], CR144[PHY_RDLV_LOAD], CR144[PHY_RDLV_RES], CR146[PHY_RDLV_RESP], CR145[PHY_RDLV_RR].
3. Program the CR101[RDLVL_CS] with the target chip select for gate training.
4. Program the leveling edge in the CR101[RDLVL_EDGE] parameter
5. Program the CR93[SW_LVL_MODE] to ’b01.
6. Set the CR93[SWLVL_START] to ’b1.

   The MC will clear the CR94[SWLVL_OP_DONE], complete the current command, inhibit the command queue and issue a precharge_all to the memory banks if necessary. An MPR write will enable read leveling for the memory (identified by the CR101[RDLVL_CS) and the PHY read level gate enable signal will be asserted to enable the PHY read levelling logic.

7. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.
8. Program delay values for each data slice X into the RDLVL_GTDL_X bits.
9. Set the CR93[SWLVL_LOAD] to ’b1.

   The MC will clear theCR94[SWLVL_OP_DONE], wait PHY read level enable signal and then load the delay values onto the PHY read level gate delay signals. After PHY read level load cycles, the PHY read level load signal will be asserted. The MC will ensure that PHY read level DLL has elapsed and then initiate a read burst. At PHY clocks after a read command cycles, the MC will load the responses from the PHY_RDLVL_RESP signals into the SWLVL_RESP_X bits for each data slice X.

10. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the int_status parameter until the operation has completed.
11. Based on the response for each slice, a higher or lower delay value should be programmed into each RDLVL_GTDL_X bits. Note that the software must track the “previous” value of the response for future evaluation.
12. Read the responses from the SWLVL_RESP_X bits. The value returned will be the value of DQ sampled by DQS for each data slice X.
13. Set the CR93[SWLVL_LOAD] to ’b1.

    The MC will clear the CR94[SWLVL_OP_DONE], load the updated delay values onto the PHY RDLVL_GTDL_X signals, wait PHY read level load and then assert the PHY read level load signal. The MC will wait PHY read level DLL cycles and ensure that PHY RDVL_RR has elapsed before issuing another read burst. After PHY RDLVL_RESP cycles, the MC will load the responses from the RDLVL_RESP signals into the SWLVL_RESP_X bits for each data slice X.

14. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt CR80[INT_STAT] until the operation has completed.
15. Read the responses from the SWLVL_RESP_X bits. The meaning of the response is based on the previous response and how the delay was changed for this iteration.
16. Repeat steps 12 through 15 until the gate is aligned to the rising edge of the read DQS for each data slice, or the delay value has reached the maximum or minimum possible.
17. The ideal delay value for this system will be the midpoint between the rising and falling edge transition points. The midpoint values should be calculated and stored in the RDLVL_DLL_X bits for each data slice X.
18. Set the CR94[SWLVL_EXIT] to ’b1.

    The MC will clear the CR94[SWLVL_OP_DONE] , perform a mode register write to disable the read leveling mode for the memory and de-assert the PHY read level gate enable signal. The command queue will be enabled for normal operation.

19. Poll the CR94[SWLVL_OP_DONE] or monitor the leveling operation complete interrupt (bit 18) in the CR80[INT_STAT] until the operation has completed.

Table 34-220. Read Leveling Responses in MC Evaluation Mode

Previous	Current	Delay Change	Suggested Action
0	0	Incremented	Increment delay value
0	0	Decremented	Decrement delay value
0	1	Incremented	Rising edge transition point has been located.
0	1	Decremented	Falling edge transition point has been located.
1	0	Incremented	Falling edge transition point has been located.
1	0	Decremented	Rising edge transition point has been located.
1	1	Incremented	Increment delay value
1	1	Decremented	Decrement delay value

34.6.16.4.2 Software Read Leveling Software Considerations

There are certain cases that the software should be prepared to consider for read leveling:

1. Depending on the resolution of the delay elements, as the DQS edge gets near the data edge, the response values may oscillate. This effect should be considered when evaluating whether a specific edge has been found. This is particularly relevant when the first delay adjustment seems to indicate an edge: several samples may be required to determine which edge has been found.

2. The software must be aware of any limitations of the delay lines in the PHY, including maximum delay values that can be programmed.
3. Once the data slices have been leveled, incremental re-leveling may be accomplished more quickly by starting with the previous value and incrementing or decrementing the delay based on the responses.
4. Ideally, the signal should be placed away from the edges of the delay line to allow flexibility in adjustment.

34.7 Initialization and Application Information

The memory controller requires a sequence for correct operation after power to the microcontroller and memory devices is stable. When power is stable, the memory controller automatically initializes the memory devices.

The procedure to initialize the memory controller is as follows:

1. Assert system reset (managed by device logic) and wait for the reset to get deasserted.
2. Issue write register commands to configure the DRAM protocols and the settings for the memory. Keep the DDR_CR00[START] de-asserted during this initialization step.
3. Assert the DDR_CR00[START]. This triggers the memory controller to execute the initialization sequence using the bits written into the registers.

The MC will set the initialization complete interrupt (bit 9) in the DDR_CR80[INT_STAT] when it is ready for commands. In addition, the user should check that the CCM_CCSR[DDRC_CLK_SEL] is enabled before accessing the DDR memory.

CAUTION

Failure to access the DDR until its clock is enabled from CCM will cause the device to hang.

Chapter 35
On-Chip One Time Programmable (OCOTP) Controller

35.1 Introduction

The OCOTP controller provides the primary mechanism for interfacing with on-chip fuses. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, security configuration, boot characteristics and various control signals requiring permanent non-volatility. For security purposes, the fuses protect the confidentiality or integrity of critical security data against both software attacks and board-level hardware attacks.

This chapter describes the on-chip One Time Programmable (OTP) Controller. It describes the block functionality and implementation in detail. In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

35.2 Overview of On-Chip OTP (OCOTP) controller

The OCOTP controller provides the following features :

- Shadow cache of fuse values loaded at reset prior to system boot.
- Ability to read and override fuse values in shadow cache (doesn’t affect fuse element).
- Ability to read fuses directly (ignoring shadow cache).
- Ability to write (program) fuses by the software
- Fuses and shadow cache bits enforcing read-protect, override-protect, and write-protect.
- Scan protection
- Provide program-protect and read-protect efuse.
- Provide overide and read protection of shadow register.
- CRC32 test for read-lock fuse content.

35.3 Top-level symbol and functional overview

The figure below shows the OCOTP system level diagram.

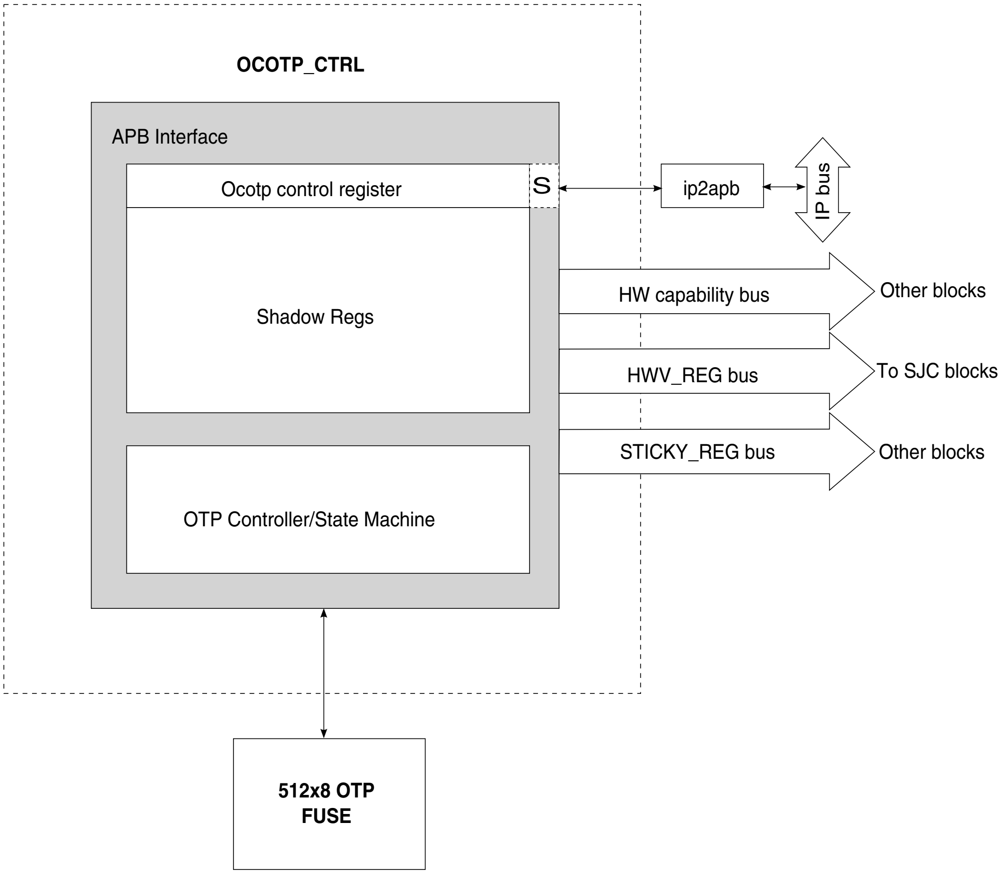

Figure 35-1. OCOTP system level diagram

35.3.1 Operation

The OCOTP provides two functions:

- Configure control registers for programming and a reading fuse word.
- Override and read shadow registers.

For an efuse, programming can only be performed on a bit and reading is based on a byte. OCOTP configuration for program and read are performed on 32-bit words for software convenience. For writes, the 32-bit word reflects the "write-mask". Bits are set to 0 by default, and when blown, are permanently set to 1. The OCOTP will program bit with 1 in the fuse word one bit by one bit. For reads, OCOTP will read four times to get 4 bytes in the fuse word in order.

This device uses nine banks of fuses. Each bank is made up of eight fuse words. Physically, there are 4k fuse bits (16 banks) present in one 512x8 efuse box. Access to the unallocated seven banks of fuses sets the ERROR bit in the OTP Controller Control Register (OCOTP_CTRL).

35.3.1.1 Fuse shadow memory footprint

The OTP memory footprint is shown in the figure below. It has 16 banks of 256 fuses (4 KB fuses in total). Each bank is arranged in 8 rows (32-bit words) with 32 fuses per row. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

NOTE

Out of 16 banks, 9 banks are used; remaining banks are reserved.

35.3.1.2 Fuse values

- All fuses are read and stored in a shadow register before the reset is de-asserted.
- It is possible to re-write, override these shadow register values based on the protection offered by the corresponding fuse locks.
- Fuse values can be read through shadow registers or by initiating a read sequence on the fuse location.

35.3.1.3 Fuse protection and overrides

- The first 32 bits of the fuse box define different locks. These locks are associated with rest of the fuses in the fuse box. These locks define the property of the fuses they are associated with.
- The lock bits are used to disable the fuses and the corresponding shadow registers.

- Except lock word, all the fuse words and shadow registers can be prohibited from programming or writing by programming corresponding lock bit in lock word.
- There are different types of locks defined and associated with various fuses. These fuses offer the following capabilities:
  - Override protect (OP): Fuse values cannot be overridden by writing into shadow registers
  - Write Protect (WP): Fuse writes are blocked
  - Read Protect (RP): Fuses values cannot be read by software (shadow registers).

35.3.1.4 Fuse blowing

Fuse blow is a simple procedure. Simple code is already available with Validation. Sophisticated drivers can be had from i.MX which will be taking care of the fuse and corresponding lock blow as well. It does not need any extra hardware/supply. High voltage needed to blow the fuse is already available within the device.

35.3.1.5 Fuse and shadow register read

All shadow registers are always readable through the APB bus except some secret key regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA. In addition OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write, read, or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully.

To read fuse word directly from fusebox correctly, complete the following steps:

1. Program OCOTP_TIMING[STROBE_READ] and OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. Refer toOTP Read/Write Timing Parameters for more information. OTP read will work at maximum bus frequencies as long as the OCOTP_TIMING parameters are set correctly.
2. Check that OCOTP_CTRL[BUSY] and OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested address to OCOTP_CTRL[ADDR].
4. Set OCOTP_READ_CTRL[READ_FUSE] to 1. OCOTP will auto read 4 bytes in requested word address in fusebox one by one. Then put read value into OCOTP_READ_FUSE_DATA register.
5. Once complete, the controller will clear OCOTP_CTRL[BUSY]. A read request to a protected or locked region will result in no OTP access and no setting of

OCOTP_CTRL[BUSY]. In addition OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read the OCOTP_READ_FUSE_DATA register to get fuse word value. OCOTP_READ_FUSE_DATA will be 0xBADABADA when OCOTP_CTRL[ERROR] is set.

35.3.1.6 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The OCOTP_LOCK register also has no shadow or fuse lock bits but it is always read only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank correctly complete the following steps:

1. Program OCOTP_TIMING[STROBE_PROG] and OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. OTP writes will work at maximum bus frequencies as long as the OCOTP_TIMING parameters are set correctly.
2. Check that OCOTP_CTRL[BUSY] and OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested fuse address to OCOTP_CTRL[ADDR] and program the unlock code into OCOTP_CTRL[WR_UNLOCK]. This must be programmed for each write access. The lock code is documented in the OCOTP_CTRLn register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the OCOTP_DATA register. This will automatically set OCOTP_CTRL[BUSY] and clear OCOTP_CTRL[WR_UNLOCK]. To protect programming same OTP bit twice, before a program the OCOTP will automatically read the fuse value and use it to mask program data. The controller will use masked program data to program a 32-bit word in the OTP per the address in OCOTP_CTRL[ADDR]. Field with 1's will result in that OTP bit being programmed. Field with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of OCOTP_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to OCOTP_CTRL[ADDR] will not affect an active write operation. It should also be noted that during the programming OCOTP_DATA will shift right (with zero fill). This shifting is required to program the OTP serially. During the write operation, OCOTP_DATA cannot be modified.

5. Once complete, the controller will clear OCOTP_CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of OCOTP_CTRL[BUSY]. In addition OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are scaled at 10 µs per word. Write latencies will be based on the number of bits being set to 1. For example, if half the fuse bits in one word are programmed, the latency is 10 µs x 16.

For further details of OTP read/write operations see [eFUSE].

OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while OCOTP_CTRL[RELOAD_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register that has been locked.
- A read is performed to from a shadow register which has been read locked.
- A program is performed to a fuse word which has that locked.
- A read is performed to from a fuse word which has that read locked.

35.3.1.7 Write postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2 µs after the clearing of OCOTP_CTRL_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes. A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY (as per Fuse shadow memory footprint).
- Once BUSY is clear, wait for 2 µs.
- Perform the next OTP operation.

35.3.2 OTP read/write timing parameters

Three timing fields in the OCOTP_TIMING register specify counter limit values that are used to time how long the state machine remains in the various states and also specify the STROBE signal timing. All are specified in ipg_clk cycles. Since the ipg_clk frequency is configurable, these timing parameters must be adjusted to yield the appropriate delay.

The OCOTP_TIMING[RELAX] field specifies how long to remain in states to meet setup and hold timing requirements. This parameter should be set by the following equation:

tRELAX = tHP_PG = (OCOTP_TIMING[RELAX]+1)/ipg_frequency > 16.2 ns

The OCOTP_TIMING[RELAX] field is used to calculate other setup and hold timing delays in addition to tHP_PG. For all timing to be met, this is the max delay that must be programmed.

Except for setup and hold timing delays, there are two timing parameters for the STROBE signal pulse width.

The OCOTP_TIMING[STROBE_PROG] field specifies the period of the STROBE signal during fuse writes and is given in units of ipg_clk cycles. The STROBE signal, tPGM, should be asserted high for a value between 9000 ns to 11000 ns. Even though a range is given for tPGM, it is advised to use a value of 10000 ns. Therefore, this field should be set according to the following equation:

tPGM = ((OCOTP_TIMING[STROBE_PROG]+1)- 2*(OCOTP_TIMING[RELAX]+1))/ ipg_frequency = 10000 ns

The OCOTP_TIMING[STROBE_READ] field specifies the period of the STROBE signal for fuse reads and is given in units of ipg_clk cycles. This field should be set according to the following equation:

tRD = ((OCOTP_TIMING[STROBE_READ]+1)- 2*(OCOTP_TIMING[RELAX] +1))/ipg_frequency > 36 ns.

The figure below illustrates the relationship between the STROBE signal in programming and reading mode and the timing register fields that affect it. The implementation uses one counter to generate the STROBE waveform within one period and a second counter counts the number of cycles to create for programming the designated word.

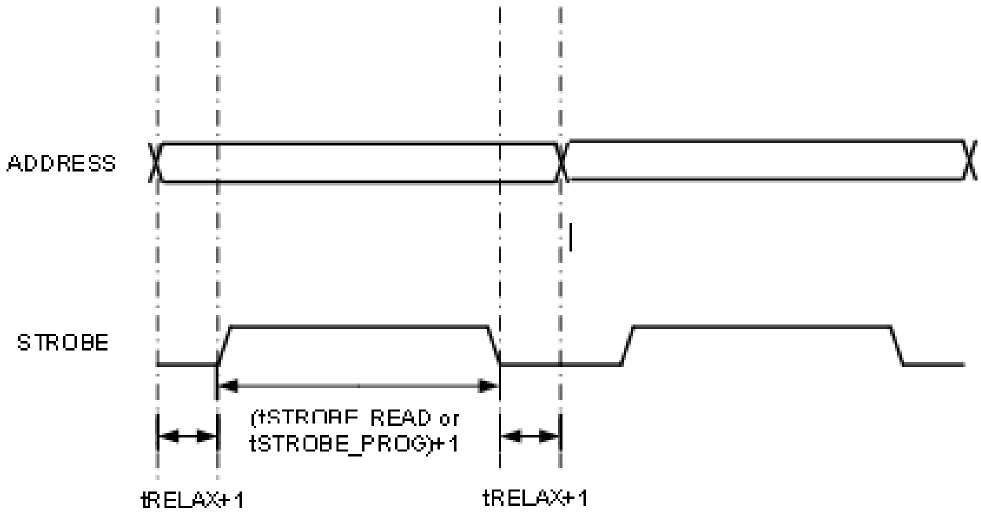

Figure 35-3. STROBE signal creation and timing

35.3.3 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time OCOTP_CTRL_BUSY is set. The load time is similar to that of a "reload shadow" operation.

35.3.4 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources.

Four JTAG security levels are shown in the table below.

Table 35-2. JTAG security level control bits

Security Mode	JTAG_SMODE	SEC_CONFIG	Description
No Debug	2'b11	x	The highest security level.
Secure JTAG	2'b01	x	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	1'b1	Low Security, all JTAG features are enabled.
SCC JTAG	2'b00	1'b0	No security.

JTAG debug access may be semi-permanently enabled by blowing the jtag_bp bit (JTAG Bypass Security). This, however, can be overridden by blowing the jtag_re bit (JTAG Security Re-enable). Blowing the jtag_bp bit effectively changes the security level from 'Secure JTAG' to 'JTAG Enable', without actually modifying the JTAG_SMODE fuses.

35.4 Fuse map

See your Freescale representative for the fuse map (fuse bit definition) of the device.

35.5.1 OTP Controller Control Register (OCOTP_CTRL*n*)

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP. The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the OCOTP_DATA register to perform write operations. Read operations to the OCOTP involve the ADDR and BUSY/ERROR bit fields, and the OCOTP_READ_CTRL register. The read value is saved in the OCOTP_READ_FUSE_DATA register.

Address: 400A_5000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	WR_UNLOCK															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved			CRC_FAIL	CRC_TEST	RELOAD_SHADOWS	Reserved	BUSY	Reserved	ADDR						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_CTRL*n* field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY). 0x3E77 **KEY** — Key needed to unlock OCOTP_DATA register.
15–13 Reserved	This field is reserved. Reserved
12 CRC_FAIL	Set by controller when the calculated CRC value is not equal to appointed CRC fuse word
11 CRC_TEST	Set this bit to calculate the CRC according to the start address and the end address in the CRC_ADDR register. It compares this with the CRC fuse word selected by the CRC address in the CRC_ADDR register, and generates the value for the CRC_FAIL flag.
10 RELOAD_ SHADOWS	Set to force re-loading the shadow registers (Hardware/Software capability and LOCK). This operation will automatically set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 Reserved	This field is reserved.

Table continues on the next page...

OCOTP_CTRL*n* field descriptions (continued)

Field	Description
8 BUSY	OTP controller status bit. When active, no new write access or read access to OTP (including RELOAD_SHADOWS) can be performed. It is cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the Hardware/Software and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7 Reserved	This field is reserved. Reserved
6–0 ADDR	OTP write and read access address register. Specifies one of 128 word address locations (0x00 - 0x7f). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not update until the access is complete.

35.5.2 OTP Controller Timing Register (OCOTP_TIMING)

This register specifies OTP Read/Write Timing Parameters

Address: 400A_5000h base + 10h offset = 400A_5010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				WAIT						STROBE_READ						RELAX				STROBE_PROG											
W																																
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0

OCOTP_TIMING field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–22 WAIT	This count value specifies time interval between auto read and write access while programming the fuse. It is given in number of ipg_clk periods.
21–16 STROBE_READ	This count value specifies the strobe period in one time read OTP. Trd = ((STROBE_READ+1)- 2*(RELAX +1)) /ipg_clk_freq. It is given in number of ipg_clk periods.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.
11–0 STROBE_PROG	This count value specifies the strobe period in one time write OTP. Tpgm = ((STROBE_PROG+1)- 2*(RELAX+1)) /ipg_clk_freq. It is given in number of ipg_clk periods.

35.5.3 OTP Controller Write Data Register (OCOTP_DATA)

The OCOTP Data Register is used for OTP Programming.

This register is used in conjunction with OCOTP_CTRL to perform one-time writes to the OTP. Please see the "Software Write Sequence" section for operating details.

Address: 400A_5000h base + 20h offset = 400A_5020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_DATA field descriptions

Field	Description
31–0 DATA	Used to initiate a write to OTP. Please see the "Software Write Sequence" section for operating details.

35.5.4 OTP Controller Read Control Register (OCOTP_READ_CTRL)

The OCOTP Register is used for OTP Read.

This register is used in conjuction with OCOTP_CTRL to perform one time read to the OTP. Please see the "FusSoftware read Sequence" section for operating details.

The OCOTP Register is used for OTP Read

Address: 400A_5000h base + 30h offset = 400A_5030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved															READ_FUSE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_READ_CTRL field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved
0 READ_FUSE	Used to initiate a read to OTP. Please see the "Fuse and Shadow Register Read" section for operating details.

35.5.5 OTP Controller Read Data Register (OCOTP_READ_FUSE_DATA)

The data read from OTP

Address: 400A_5000h base + 40h offset = 400A_5040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA

OCOTP_READ_FUSE_DATA field descriptions

Field	Description
31–0 DATA	The data read from OTP

35.5.6 Software Controllable Set Register (OCOTP_SCS*n*)

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their defualt values after POR.

Address: 400A_5000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	LOCK	SPARE														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SPARE															HAB_JDE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_SCS*n* field descriptions

Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through software programming. This bit is only reset after a POR is issued.
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properlay signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR. 0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms). 1 JTAG debugging is enabled by the HAB (though this signal may be gated off)

35.5.7 OTP Controller CRC address (OCOTP_CRC_ADDR)

This register is used to calculate as part of the CRC validation. See the CRC32 test for read locking fuse area

Address: 400A_5000h base + 70h offset = 400A_5070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved													CRC_ ADDR			DATA_END_ADDR								DATA_START_ADDR							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_CRC_ADDR field descriptions

Field	Description
31–19 Reserved	This field is reserved. Reserved
18–16 CRC_ADDR	Address of 32-bit CRC result for comparing
15–8 DATA_END_ ADDR	Start address of fuse location for CRC calculation
7–0 DATA_START_ ADDR	End address of fuse location for CRC calculation

35.5.8 OTP Controller CRC Value Register (OCOTP_CRC_VALUE)

The CRC32 value is based on CRC_ADDR.

Address: 400A_5000h base + 80h offset = 400A_5080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA

OCOTP_CRC_VALUE field descriptions

Field	Description
31–0 DATA	The CRC32 value based on CRC_ADDR

35.5.9 OTP Controller Version Register (OCOTP_VERSION)

This register always returns the OCOTP module version number.

Address: 400A_5000h base + 90h offset = 400A_5090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

35.5.10 Value of OTP Bank0 Word0 (Lock controls) (OCOTP_LOCK)

Copied from the OTP automatically after reset. Can be re-loaded by setting _OCOTP_CTRL[RELOAD_SHADOWS]

This register shadowed the OTP fuse BANK 0, word 0(ADDR 0x00). This register is always read/write lock. The corresponding fuse word is always read lock.

Address: 400A_5000h base + 400h offset = 400A_5400h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_LOCK field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–28 CRC_GP_HI_ LOCK	Status of shadow register write and read, OTP program and read lock for upper 128 bits CRC region. When bit 1 is set, the reading and writing of this region's OTP fuse and reading of shadow register are blocked.When bit 0 is set, the writing of this region's shadow register and OTP fuse are blocked.
27–26 CRC_GP_LO_ LOCK	Status of shadow register write and read, OTP program and read lock for lower 128 bits CRC region. When bit 1 is set, the reading and writing of this region's OTP fuse and reading of shadow register are blocked.When bit 0 is set, the writing of this region's shadow register and OTP fuse are blocked.
25–23 Reserved	This field is reserved. Reserved
22 MISC_CONF_ LOCK	Status of shadow register and OTP write lock for misc_conf region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
21–20 PMU_LOCK	Status of shadow register and OTP write lock for PMU region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
19–18 ANALOG_LOCK	Status of shadow register and OTP write lock for analog region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

Table continues on the next page...

OCOTP_LOCK field descriptions (continued)

Field	Description
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–15 Reserved	This field is reserved. Reserved
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–12 GP2_LOCK	Lock for General Purpose fuse register #2 (GP2) Status of shadow register and OTP write lock for GP2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
11–10 GP1_LOCK	Lock for General Purpose fuse register #1 (GP1) Status of shadow register and OTP write lock for GP1 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
9–8 MAC_ADDR_ LOCK	Lock MAC_ADDR fuses. Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
7 Reserved	Reserved. This field is reserved. Reading this bit will get a 1.
6 SJC_RESP_ LOCK	Status of shadow register read and write, OTP read and write lock for sjc_resp region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
5–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 BOOT_CFG_ LOCK	Perform lock on BOOT related fuses. Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
1–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

35.5.11 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP_CFG0)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS]

This register shadows the OTP fuse BANK 0, word 1 (ADDR 0x01). This register is read-only after TESTER_LOCK[1] is set. The corresponding fuse word is also read-only after TESTER_LOCK[0] is set.

Address: 400A_5000h base + 410h offset = 400A_5410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_CFG5 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 JTAG_HEO	JTAG HAB Enable Override. Disallows HAB JTAG enabling. The HAB may normally enable JTAG debugging by means of the HAB_JDE-bit in the OCOTP SCS register. The JTAG_HEO-bit can override this behavior. 0 HAB may enable JTAG debug access 1 HAB JTAG enable is overridden (HAB may not enable JTAG debug access)
26 KTE	Kill Trace Enable. Enables tracing capability on ETM, and other modules. 0 Bus tracing is allowed 1 Bus tracing is allowed in case security state as defined by Secure JTAG allows it (for example, JTAG_ENABLE or NO_DEBUG)
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–22 JTAG_SMODE	JTAG Security Mode. Controls the security mode of the JTAG debug interface. 00 JTAG enable mode 01 Secure JTAG mode 11 No debug mode
21 WDOG_ENABLE	Watchdog Enable. Used to specify whether to enable / not watchdog at boot. 0 Watch-Dog is disabled. 1 Watch-Dog is enabled.

Table continues on the next page...

OCOTP_CFG5 field descriptions (continued)

Field	Description
20 SJC_DISABLE	Secure JTAG Controller module. This fuse is used to create highest JTAG security level, where JTAG is totally blocked. 0 Secure JTAG Controller is enabled 1 Secure JTAG Controller is disabled
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 Reserved	This field is reserved.
17–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 BT_FUSE_SEL	Determines, whether using fuses for boot configuration, or GPIO /Serial loader. 0=Boot mode configuration is taken from GPIOs. 1=Boot mode configuration is taken from fuses. 0 - Boot using Serial Loader (USB) 1- Boot mode configuration is taken from fuses. If boot_mode="00" (Development) If boot_mode="10" (Production)
3 DIR_BT_DIS	Direct Boot Disable. 0 Enable 1 Disable
2 Reserved	This field is reserved.
1 SEC_CONFIG	Security Configuration (with SEC_CONFIG[0]). 00 - FAB (Open) 01 - Open - allows any code to be flashed and executed, even if it has no valid signature. 1x - Closed (Security On)
0 Reserved	This field is reserved.

35.5.15 Value of OTP Bank1 Word7 (General Purpose Customer Defined Info.) (OCOTP_ANA2)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS]

This register shadowed the OTP fuse BANK 1, word 7 (ADDR 0x0F). This register is read-only after ANALOG_LOCK[1] is set. The corresponding fuse word is also read-only after ANALOG_LOCK[0] is set.

Address: 400A_5000h base + 4F0h offset = 400A_54F0h

Chapter 36
12-bit Digital-to-Analog Converter (DAC)

36.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

36.2 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from 1⁄4096 V_{in} to V_{in}, and the step is 1⁄4096 V_{in}, where V_{in} is the input voltage.
- V_{in} can be selected from two reference sources
- Static operation in Normal Stop mode
- 16-word data buffer supported with configurable watermark and multiple operation modes
- DMA support

36.3 Block diagram

The block diagram of the DAC module is as follows:

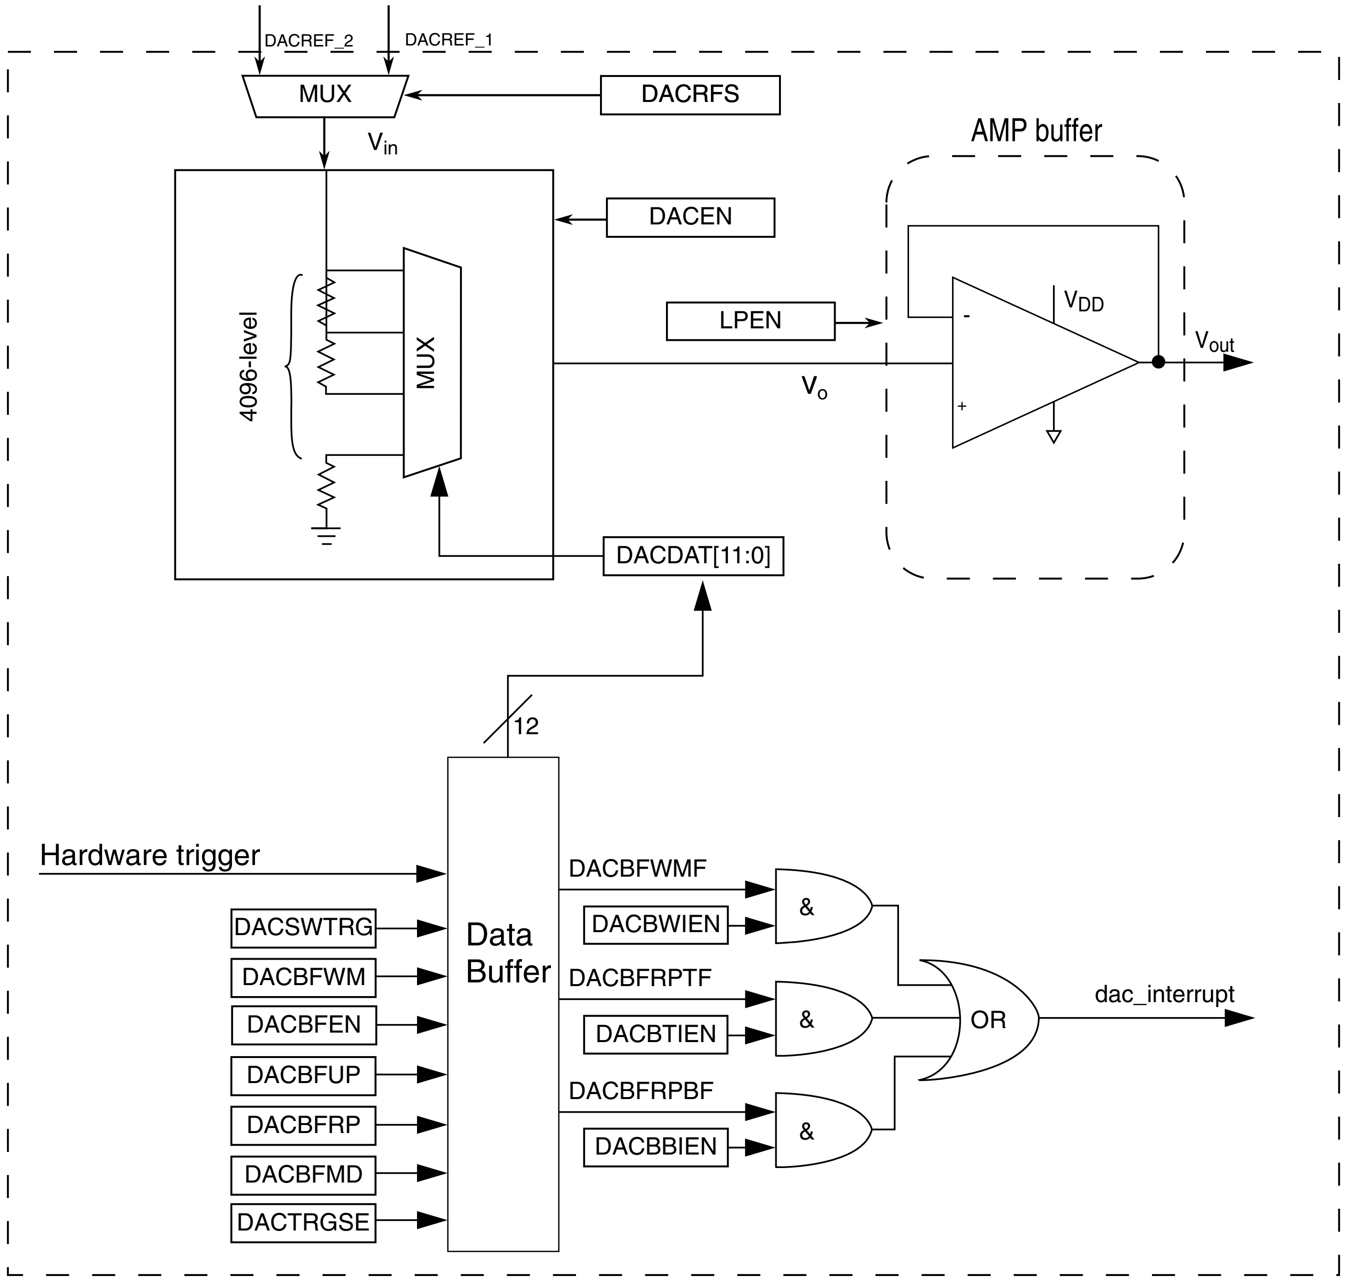

Figure 36-1. DAC block diagram

36.4 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

DAC memory map

DACx_DAT*n* field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–16 DATA1	When the DAC buffer is not enabled, this field controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DAC\_DATn[DATA1])/4096$ When the DAC buffer is enabled, this field is mapped to the 16-word buffer.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 DATA0	When the DAC buffer is not enabled, this field controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DAC\_DATn[DATA0])/4096$ When the DAC buffer is enabled, this field is mapped to the 16-word buffer.

36.4.2 DAC Status and Control Register (DACx_STATCTRL)

If DMA is enabled, the flags can be cleared automatically by DMA when the DMA request is done. Writing 0 to a field clears it whereas writing 1 has no effect. After reset, DACBFRPTF is set and can be cleared by software, if needed. The flags are set only when the data buffer status is changed.

Address: Base address + 20h offset

DACx_STATCTRL field descriptions

Field	Description
31–28 DACBFRP	DAC Buffer Read Pointer Keeps the current value of the buffer read pointer.
27–24 DACBFUP	DAC Buffer Upper Limit Selects the upper limit of the DAC buffer. The buffer read pointer cannot exceed it.
23 DMAEN	DMA Enable Select 0 DMA is disabled. 1 DMA is enabled. When DMA is enabled, the DMA request will be generated by original interrupts. The interrupts will not be presented on this module at the same time.

Table continues on the next page...

DACx_STATCTRL field descriptions (continued)

Field	Description
22–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–19 DACBFWM	DAC Buffer Watermark Select Controls when DACBFWMF will be set. When the DAC buffer read pointer reaches the word defined by this field, which is 1–4 words away from the upper limit (DACBUP), DACBFWMF will be set. This allows user configuration of the watermark interrupt. 00 1 word 01 2 words 10 3 words 11 4 words
18–17 DACBFMD	DAC Buffer Work Mode Select 00 Normal mode 01 Swing mode 10 One-Time Scan mode 11 Reserved
16 DACBFEN	DAC Buffer Enable 0 Buffer read pointer is disabled. The converted data is always the first word of the buffer. 1 Buffer read pointer is enabled. The converted data is the word that the read pointer points to. It means converted data can be from any word of the buffer.
15 DACEN	DAC Enable Starts the Programmable Reference Generator operation. 0 The DAC system is disabled. 1 The DAC system is enabled.
14 DACRFS	DAC Reference Select 0 The DAC selects DACREF_1 as the reference voltage. 1 The DAC selects DACREF_2 as the reference voltage.
13 DACTRGSEL	DAC Trigger Select 0 The DAC hardware trigger is selected. 1 The DAC software trigger is selected.
12 DACSWTRG	DAC Software Trigger Active high. This is a write-only field, which always reads 0. If DAC software trigger is selected and buffer is enabled, writing 1 to this field will advance the buffer read pointer once. 0 The DAC soft trigger is not valid. 1 The DAC soft trigger is valid.
11 LPEN	DAC Low Power Control **NOTE:** See the 12-bit DAC electrical characteristics of the device data sheet for details on the impact of the modes below.

Table continues on the next page...

DACx_STATCTRL field descriptions (continued)

Field	Description
	0 High-Power mode 1 Low-Power mode
10 DACBWIEN	DAC Buffer Watermark Interrupt Enable 0 The DAC buffer watermark interrupt is disabled. 1 The DAC buffer watermark interrupt is enabled.
9 DACBTIEN	DAC Buffer Read Pointer Top Flag Interrupt Enable 0 The DAC buffer read pointer top flag interrupt is disabled. 1 The DAC buffer read pointer top flag interrupt is enabled.
8 DACBBIEN	DAC Buffer Read Pointer Bottom Flag Interrupt Enable 0 The DAC buffer read pointer bottom flag interrupt is disabled. 1 The DAC buffer read pointer bottom flag interrupt is enabled.
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 DACBFWMF	DAC Buffer Watermark Flag 0 The DAC buffer read pointer has not reached the watermark level. 1 The DAC buffer read pointer has reached the watermark level.
1 DACBFRPTF	DAC Buffer Read Pointer Top Position Flag 0 The DAC buffer read pointer is not zero. 1 The DAC buffer read pointer is zero.
0 DACBFRPBF	DAC Buffer Read Pointer Bottom Position Flag 0 The DAC buffer read pointer is not equal to DACBFUP. 1 The DAC buffer read pointer is equal to DACBFUP.

36.5 Functional description

The 12-bit DAC module can select one of the two reference inputs—DACREF_1 and DACREF_2 as the DAC reference voltage, V_{in} by STATCTRL[DACRFS]. See the module introduction for information on the source for DACREF_1 and DACREF_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from V_{in} to $V_{in}/4096$, and the step is $V_{in}/4096$.

36.5.1 DAC data buffer operation

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in DAT0 to analog output voltage.

When both the DAC and the buffer are enabled, the DAC converts the data in the data buffer to analog output voltage. The data buffer read pointer advances to the next word whenever any hardware or software trigger event occurs. Refer to Introduction for the hardware trigger connection.

The data buffer can be configured to operate in Normal mode, Swing mode, or One-Time Scan mode. When the buffer operation is switched from one mode to another, the read pointer does not change. The read pointer can be set to any value between 0 and STATCTRL[DACBFUP] by writing STATCTRL[DACBFRP].

36.5.1.1 DAC data buffer interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer. STATCTRL[DACBFRPBF] is set when the DAC buffer read pointer reaches the DAC buffer upper limit, that is, STATCTRL[DACBFRP] = STATCTRL[DACBFUP]. STATCTRL[DACBFRPTF] is set when the DAC read pointer is equal to the start position, 0. Finally, STATCTRL[DACBFWMF] is set when the DAC buffer read pointer has reached the position defined by STATCTRL[DACBFWM]. STATCTRL[DACBFWM] can be used to generate an interrupt when the DAC buffer read pointer is between 1 to 4 words from STATCTRL[DACBFUP].

36.5.1.2 Modes of DAC data buffer operation

The following table describes the different modes of data buffer operation for the DAC module.

Table 36-34. Modes of DAC data buffer operation

Modes	Description
Buffer Normal mode	This is the default mode. The buffer works as a circular buffer. The read pointer increases by one, every time the trigger occurs. When the read pointer reaches the upper limit, it goes to 0 directly in the next trigger event.
Buffer Swing mode	This mode is similar to the normal mode. However, when the read pointer reaches the upper limit, it does not go to 0. It will descend by 1 in the next trigger events until 0 is reached.
Buffer One-time Scan mode	The read pointer increases by 1 every time the trigger occurs. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it will increase to the upper address and stop there again. **NOTE:** If the software set the read pointer to the upper limit, the read pointer will not advance in this mode.

36.5.2 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

36.5.3 Resets

During reset, the DAC is configured in the default mode and is disabled.

36.5.4 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

Table 36-35. Modes of operation

Modes of operation	Description
Wait mode	The DAC will operate normally, if enabled.
Stop mode	If enabled, the DAC module continues to operate in Normal Stop mode and the output voltage will hold the value before stop. In low-power stop modes, the DAC is fully shut down.

NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

Chapter 37 ADC-Digital-12b-1MSPS-SAR

37.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The 12-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

37.3 Features List

The features of the ADC-Digital are as follows:

- Configuration registers
  - 32-bit, word aligned, byte enabled registers. (Byte and Halfword access is not supported)
- Linear successive approximation algorithm with up to 12-bit resolution with 10/11 bit accuracy.
- Up to 10 ENOB (dedicated Single Ended Channels)
- Up to 1MS/s sampling rate
- Up to 16 single-ended external analog inputs
- Single or continuous conversion (automatic return to idle after single conversion)
- Output Modes: (in right-justified unsigned format)
  - 12-bit,
  - 10-bit
  - 8-bit
- Configurable sample time and conversion speed/power
- Conversion complete and hardware average complete flag and interrupt
- Input clock selectable from up to four sources
- Asynchronous clock source for lower noise operation with option to output the clock
- Selectable asynchronous hardware conversion trigger with hardware channel select
- Selectable voltage reference, Internal, External, or Alternate
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Operation in low power modes for lower noise operation
- Temperature sensor
- Hardware average function
- Self-calibration mode

37.4 Operation mode (ADC enable/disable)

By default, the ADC is in disabled mode. In this state, no conversion or other actions occur. All of the ADC control registers are accessible in this state through an access bus interface.To enable the ADC, required configurations should be done by programming the ADC configuration registers.

37.5 ADC module interface

The ADC is connected to many interfaces such as the clocks and reset, access bus, voltage references, interrupt controller, hardware triggers, ADC pin control, and analog I/F as shown in the following figure.

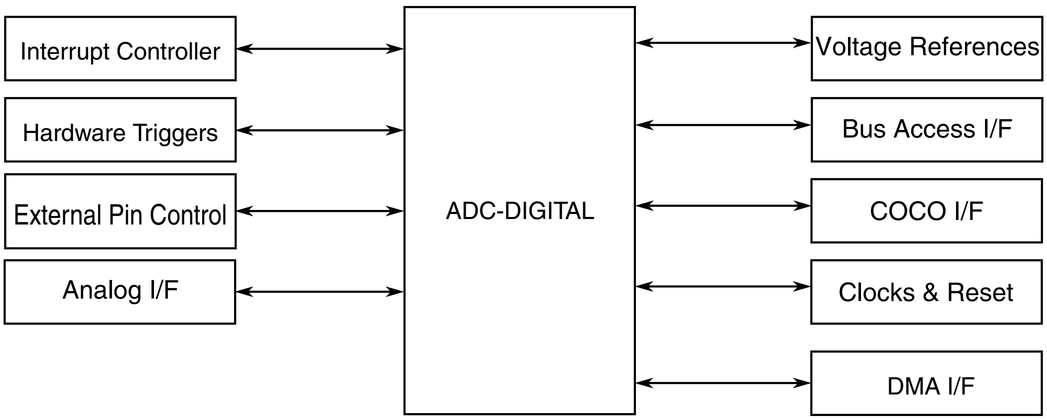

Figure 37-2. ADC-Digital module interface

The number of interrupt vectors and the trigger sources (modules that can trigger and ADC conversion) are chip-specific. Please refer to the Chip Configuration chapter for this information.

37.6 External Signal Description

The ADC module supports up to 16 single-ended inputs.

The ADC also requires four supply/reference/ground connections.

Name	Function
DADP0-DADP15	Analog Channel Inputs
ADP_16t23	Separate Analog Channel Inputs

Table continues on the next page...

Name	Function
V_{REFSH}	Voltage Reference Select High
V_{REFSL}	Voltage Reference Select Low
V_{DDAD}	Analog power supply
V_{SSAD}	Analog ground

37.7 Memory map and register definition

The ADC-Digital contains 32-bit, word aligned, byte enables registers; byte or half word access are not supported. All configuration registers are accessible via 32-bit access bus Interface. Write access to reserved locations have no impact while read access to reserved locations always return 0.

NOTE

No protection or indication mechanism is available (for example, 32-bit access starting with address offset value 0x01 or 0x02 or 0x03). The ADC does not check for correctness of the programmed values in the registers and the programmer must ensure that correct values are being written.

37.7.1 Control register for hardware triggers (ADCx_HC0)

ADC_HC0 is for use only in hardware trigger mode. The ADC_HC0 to ADC_HCn(n=0,1) registers have identical fields, and are used to control ADC operation. At any one point in time, only one of the ADC_HC0 to ADC_HCn(n=0,1) registers is actively controlling ADC conversions. Updating ADC_HC0 while ADC_HCn(n=0,1) is actively controlling a conversion is allowed (and vice-versa for any of the ADC_HCn (n=0,1) registers). Writing ADC_HC0 while ADC_HC0 is actively controlling a conversion aborts the current conversion. In software trigger mode (ADTRG=0), writes to ADC_HC0 subsequently initiates a new conversion (if the ADCH bits are equal to a value other than all 1s). Similarly, writing any of the ADC_HCn(n=0,1) registers while that specific ADC_HC register is actively controlling a conversion aborts the current conversion. ADC_HC1 register is not used for software trigger operation and therefore writes to any of them do not initiate a new conversion.

ADCx_HS field descriptions

Field	Description
31–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 COCO1	See description for COCO0.
0 COCO0	Conversion Complete Flag The COCOn flag is a read-only bit that is set each time a conversion is completed when the compare function is disabled (ADC_GC[ACFE]=0) and the hardware average function is disabled (ADC_GC[AVGE]=0). When the compare function is enabled (ADC_GC[ACFE]=1), the COCOn flag is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled (ADC_GC[AVGE]=1), the COCOn flag is set upon completion of the selected number of conversions (determined by the ADC_CFG[AVGS] field). The COCO0 flag will also set at the completion of a Calibration and Test sequence. A COCOn bit is cleared when the respective ADC_HCn is written or when the respective ADC_Rn is read.

37.7.4 Data result register for HW triggers (ADCx_R0)

Contains the result of an ADC conversion of the channel selected by the respective hardware trigger and channel control register (ADC_HC0:ADC_HCn). For every ADC_HC0:ADC_HCn status and channel control register, there is a respective ADC_R0:ADC_Rn data result register. Unused bits in the ADC_Rn register are cleared in unsigned right justified modes. For example when configured for 10-bit single-ended mode, D[31:10] are cleared. The table below describes the behavior of the data result registers in the different modes of operation.

Table 37-21. Data Result Register Description

Conversion Mode	Data Result Register bits																Format
	D31	D30	....	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0

ADCx_CFG field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 OVWREN	Data Overwrite Enable Controls the overwriting of the next converted Data onto the existing (previous) unread data into the Data result register. 1 Enable the overwritting. 0 Disable the overwritting. Existing Data in Data result register will not be overwritten by subsequent converted data.
15–14 AVGS	Hardware Average select Determines how many ADC conversions will be averaged to create the ADC average result. This functionality is activated when ADC_GC[AVGE] = 1. 00 4 samples averaged 01 8 samples averaged 10 16 samples averaged 11 32 samples averaged
13 ADTRG	Conversion Trigger Select Selects the type of trigger used for initiating a conversion. Two types of trigger are selectable: software trigger and hardware trigger. When software trigger is selected, a conversion is initiated following a write to ADC_HC0. When hardware trigger is selected, a conversion is initiated following the assertion of a pulse on Alternate Hardware trigger input along with the assertion of the enable of respective the hardware Triggers input .

Table continues on the next page...

ADCx_CFG field descriptions (continued)

Field	Description
	0 Software trigger selected 1 Hardware trigger selected
12–11 REFSEL	Voltage Reference Selection Selects the voltage reference source used for conversions. Refer to the chip configuration chapter's ADC section for details of these field definitions for this chip. 00 Selects VREFH/VREFL as reference voltage. 01 Selects VALTH/VALTL as reference voltage. 10 Selects VBGH/VBGL as reference voltage. 11 Reserved.
10 ADHSC	High Speed Configuration This bit configures the ADC for high speed operation. The internal ADC clock is higher than normal. 0 Normal conversion selected. 1 High speed conversion selected.
9–8 ADSTS	Defines the sample time duration. This has two modes, short and long. When long sample time is selected (ADLSMP=1) this works for long sample time otherwise this works for short sample. This allows higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required. 00 Sample period (ADC clocks) = 2 if ADLSMP=0b Sample period (ADC clocks) = 12 if ADLSMP=1b 01 Sample period (ADC clocks) = 4 if ADLSMP=0b Sample period (ADC clocks) = 16 if ADLSMP=1b 10 Sample period (ADC clocks) = 6 if ADLSMP=0b Sample period (ADC clocks) = 20 if ADLSMP=1b 11 Sample period (ADC clocks) = 8 if ADLSMP=0b Sample period (ADC clocks) = 24 if ADLSMP=1b
7 ADLPC	Low-Power Configuration Puts the ADC hard block into low power mode and reduces the comparator enable period by controlling its timing in the SAR controller block towards the anlong hard block. The signal indicating low power mode to the Analog block is asserted when this bit is set. 0 ADC hard block not in low power mode. 1 ADC hard block in low power mode.
6–5 ADIV	Clock Divide Select Selects the divide ratio used by the ADC to generate the internal clock ADCK. 00 Input clock 01 Input clock / 2 10 Input clock / 4 11 Input clock / 8

Table continues on the next page...

ADCx_CFG field descriptions (continued)

Field	Description
4 ADLSMP	Long Sample Time Configuration Selects between different sample times based on the ADC_CFG[ADSTS] field. This bit adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. If high conversion rates are not required, longer sample times can also be used to lower overall power consumption when continuous conversions are enabled. When ADLSMP=1, the Long Sample Time mode is selected and the time is defined by ADSTS[1:0] of the ADC_CFG register. 0 Short sample mode. 1 Long sample mode.
3–2 MODE	Conversion Mode Selection Used to set the ADC resolution mode. 00 8-bit conversion 01 10-bit conversion 10 12-bit conversion 11 Reserved
1–0 ADICLK	Input Clock Select Selects the input clock source to generate the internal clock ADCK. 00 IPG clock 01 IPG clock divided by 2 10 Alternate clock (ALTCLK) 11 Asynchronous clock (ADACK)

37.7.7 General control register (ADCx_GC)

Controls the calibration, continuous convert, hardware averaging functions, conversion active, hardware/software trigger select, compare function and voltage reference select of the ADC module.

Address: Base address + 18h offset

Reset									0	0	0	0	0	0	0	0

ADCx_GC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CAL	Calibration CAL begins the calibration sequence when set. This bit stays set while the calibration is in progress and is cleared when the calibration sequence is complete. The ADC_GS[CALF] bit must be checked to determine the result of the calibration sequence. Once started, the calibration routine cannot be interrupted by writes to the ADC registers or the results will be invalid and the ADC_GS[CALF] bit will set. Setting the CAL bit will abort any current conversion.
6 ADCO	Continuous Conversion Enable Enables continuous conversions. 0 One conversion or one set of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion. 1 Continuous conversions or sets of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion.
5 AVGE	Hardware average enable Enables the hardware average function of the ADC. 0 Hardware average function disabled 1 Hardware average function enabled
4 ACFE	Compare Function Enable Enables the compare function. 0 Compare function disabled 1 Compare function enabled
3 ACFGT	Compare Function Greater Than Enable Configures the compare function to check the conversion result relative to the compare value register (ADC_CV) based upon the value of ACREN (bit 2 in ADC_GC register). The ACFE bit must be set for ACFGT to have any effect. 0 Configures "Less Than Threshold, Outside Range Not Inclusive and Inside Range Not Inclusive" functionality based on the values placed in the ADC_CV register. 1 Configures "Greater Than Or Equal To Threshold, Outside Range Inclusive and Inside Range Inclusive" functionality based on the values placed in the ADC_CV registers.
2 ACREN	Compare Function Range Enable Configures the compare function to check the conversion result of the input being monitored is either between or outside the range formed by the compare values in register (ADC_CV) determined by the value of ACFGT. The ACFE bit must be set for ACFGT to have any effect. 0 Range function disabled. Only the compare value 1 of ADC_CV register (CV1) is compared. 1 Range function enabled. Both compare values of ADC_CV registers (CV1 and CV2) are compared.
1 DMAEN	DMA Enable Enables the DMA logic.

Table continues on the next page...

ADCx_GC field descriptions (continued)

Field	Description
	0 DMA disabled (default) 1 DMA enabled
0 ADACKEN	Asynchronous clock output enable Enables the ADC's asynchronous clock source and the clock source output regardless of the conversion and input clock select (ADC_CFG[ADICLK]) settings of the ADC. Based on MCU configuration, the asynchronous clock may be used by other modules (see module introduction section). Setting this bit allows the clock to be used even while the ADC is idle or operating from a different clock source. Also, latency of initiating a single or first-continuous conversion with the asynchronous clock selected is reduced since the ADACK clock is already operational. 0 Asynchronous clock output disabled; Asynchronous clock only enabled if selected by ADICLK and a conversion is active. 1 Asynchronous clock and clock output enabled regardless of the state of the ADC

37.7.8 General status register (ADCx_GS)

Controls the calibration, continuous convert, hardware averaging functions, conversion active, hardware/software trigger select, compare function and voltage reference select of the ADC module.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADCx_GS field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 AWKST	Asynchronous wakeup interrupt status Holds the status of asynchronous interrupt status that occured during stop mode. This bit is set when ipg_stop is deasserted and ipg_clk has started. It is cleared by writing '1' to it. Clearing this bit also deasserts the Asynchronous interrupt to CPU. 1 Asynnchronous wake up interrupt occured in stop mode. 0 No asynchronous interrupt.
1 CALF	Calibration Failed Flag Displays the result of the calibration sequence. The calibration sequence will fail if Hardware Trigger is selected (i.e. ADC_CFG[ADTRG] = 1), or any ADC register is written, or any stop mode is entered before the calibration sequence completes. The CALF bit is cleared by writing a 1 to it. 0 Calibration completed normally. 1 Calibration failed. ADC accuracy specifications are not guaranteed.
0 ADACT	Conversion Active Indicates that a conversion or hardware averaging is in progress. ADACT is set when a conversion is initiated and cleared when a conversion is completed or aborted. 0 Conversion not in progress. 1 Conversion in progress.

37.7.9 Compare value register (ADCx_CV)

Contains compare values used to compare with the conversion result when the compare function is enabled (ADC_GC[ACFE]=1). The compare values are right justified as shown Figure . Therfore, the compare function only uses the compare value register bits that are related to the ADC mode of operation. (e.g. in 8 bit mode, CV1 = ADC_CV[7:0] and CV2 = ADC_CV[23:16], similarly in 10 bit mode, CV1 = ADC_CV[9:0] and CV2 = ADC_CV[25:16] etc.) The compare value 2 in this register is utilized only when the compare range function is enabled (ADC_GC[ACREN]=1).

Address: Base address + 20h offset

27–16 CV2	Compare Value 2 Contains a compare value used to compare with the conversion result when the compare function and compare range function are enabled (ADC_GC[ACFE]=1, ADC_GC[ACREN]=1).
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 CV1	Compare Value 1 Contains a compare value used to compare with the conversion result when the compare function ais enabled (ADC_GC[ACFE]=1).

37.7.10 Offset correction value register (ADCx_OFS)

Contains the user-defined offset error correction value. This register is 13 bits wide. The value in the most significant bit (13th bit) is the operation bit. If this bit is ‘0’ then the value in the other 12 bits is added with the converted result value to generate final result to be loaded into ADC_Rn; if this bit is ‘1’ then this field is subtracted from converted value to generate final result (ADC_Rn).

11–0 OFS	Offset value User configurable offset value.

37.7.11 Calibration value register (ADCx_CAL)

Contains calibration information that is generated by the calibration function. This register contains a calibration value of four bits(CAL[3:0]); this is automatically set once the self calibration sequence is done (ADC_SC[CAL] bit is cleared). If this register is written to by the user after calibration, the linearity error specifications may not be met.

0 ADPC0	ADC Pin Control 0 Controls the pin associated with channel AD0. 0 AD0 pin I/O control enabled 1 AD0 pin I/O control disabled

37.8 Functional Description

There are three possible states which ADC module can be in

1. Disabled State
2. Idle state
3. Performing conversions

Disabled State:

The ADC module is disabled during reset, stop mode (if internal clock is not selected as source of Clock), or when the ADCH bits of the hardware control (ADC_HCn) registers are all high.

Idle State:

The module is idle when a conversion has completed and another conversion has not been initiated. When idle and the asynchronous clock output enable is disabled (ADACKEN=0), the module is in its lowest power state.

Conversion State:

The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications the ADC module must be calibrated using the on chip calibration function. Calibration is recommended to be done after any reset.

When the conversion is completed, the result is placed in the data result registers (ADC_Rn). The conversion complete flag (COCOn) bits in Hardware Status register is/are then set and an interrupt is generated, if the respective conversion complete interrupt has been enabled (ADC_HCn[AIEN]=1).

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the compare value registers. The compare function is enabled by setting the ACFE (ADC compare function Enable) bit in ADC general control register.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting the AVGE bit in ADC general control register.

37.8.1 Clock Select and Divide Control

The ADC digital module has three clock sources

- IPG clock
- Alternate Clock (ALTCLK) is connected to the signal described in the ADC section of the chip configuration chapter.
- Internal clock (ADACK) is a dedicated clock used only by the ADC.

ADC digital block generates IPG clock/2 by internally dividing the IPG clock. The final clock is chosen from the following clocks.

- IPG clock
- IPG clock divided by 2
- ALTCLK
- ADACK

Out of the above four clocks one is chosen depending on the configuration of ADCLK[1:0] bits of ADC_CFG. This chosen clock is divided depending on the configuration of ADIV[1:0] bits of ADC_CFG. The final generated clock is used as conversion clock for ADC.

ADICLK	Selected Clock Source
00	IPG clock
01	IPG clock divided by 2
10	Alternate clock (ALTCLK)
11	Asynchronous clock (ADACK)

- The IPG clock. This is the default selection following reset.
- The IPG clock divided by two. For higher IPG clock rates, this allows a maximum divide by 16 of the IPG clock with using the ADIV bits.
- ALTCLK, as defined for this chip.
- The asynchronous clock (ADACK). This clock is generated from a clock source within the ADC module. Conversions are possible using ADACK as the input clock source while the MCU is in stop mode.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by the ADIV bits and can be divide-by 1, 2, 4, or 8.

37.8.2 Input Select and Pin Control

The pin control registers (ADC_PC) disable the I/O port control of the pins used as analog inputs. When a pin control register bit is set, the following conditions are forced for the associated MCU pin:

- The output buffer is forced to its high impedance state.
- The input buffer is disabled. A read of the I/O port returns a zero for any pin with its input buffer disabled.
- The pullup is disabled.

37.8.3 Voltage Reference Selection

The ADC can be configured to accept one of three voltage reference pairs as the reference voltages (V_{REFSH} and $_{VREFSL}$) used for conversions. Each pair contains a positive reference which must be between the minimum Ref Voltage High and V_{DDAD}, and a ground reference which must be at the same potential as V_{SSAD}.The three pairs are external (V_{REFH} and V_{REFL}), alternate (V_{ALTH} and V_{ALTL}) and the internal bandgap (V_{BGH} and V_{BGL}). These voltage references are selected using the REFSEL bits in the ADC_CFG register.The alternate (V_{ALTH} and V_{ALTL}) voltage reference pair may select additional external pins or internal sources depending on MCU configuration.

37.8.4 Hardware Triggering and Channel Selection

The ADC module has a trigger input (known as alternate Trigger) which provides asynchronous hardware conversion trigger when the ADTRG bit in ADC configuration register (ADC_CFG) is set and any of the external hardware trigger select is high.

To be reliably captured, the Alternate trigger pulse must be high for sufficient time to satisfy clocking requirement of capturing Flop and the external hardware trigger select event must be set for sufficient time before and after the positive edge of Alternate trigger pulse to meet the setup / hold requirement of capturing flop.

If an external hardware trigger select event gets asserted during a conversion it must stay asserted until end of current conversion and remain set until the receipt of the an Alternate Trigger to initiate a new conversion.

When the Alternate trigger source is available and hardware triggering is enabled (ADC_CFG[ADTRG]=1), a conversion is initiated on the rising edge of the Alternate Trigger after a external hardware trigger select event has occurred.

If a conversion is in progress when a rising edge of a trigger occurs, the rising edge is ignored. In continuous convertion configuration, only the initial rising edge to launch continuous conversions is observed and until conversion gets aborted the ADC will continue to do conversions on the same ADC Hardware Trigger Control register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The channel selected for the conversion will depend on the settings of active Hardware Trigger register field ADC_HCn[ADCH] of enabled external hardware trigger.

NOTE

Asserting more than one external hardware trigger select signal at the same time will result in unknown results. To avoid this, only select one external hardware trigger select signal prior to the next intended conversion.

When the conversion is completed, the result is placed in the data registers associated with the external hardware trigger received (active trigger selects ADC_Rn). The conversion complete flag associated with the external hardware trigger received (ADC_HS[COCOn]) is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled (ADC_HCn[AIEN]=1).

37.8.5 Conversion Control

Conversions is performed as determined by the MODE bits in ADC_CFG register.

Conversions can be initiated by a either by a software trigger or hardware trigger. In addition, the ADC module can be configured for low power operation, long sample time, continuous conversion, hardware average and automatic compare of the conversion result to a software determined compare value.

37.8.5.1 Initiating Conversions

A conversion is initiated:

- Following a write to ADC_HC1 (with ADCHn bits not all 1's) and if software triggered operation is selected (ADTRG=0).

- Following a hardware trigger event if hardware triggered operation is selected (ADTRG=1) and a external hardware trigger select event has occurred. The channel selected will depend on the active trigger select signal active selects ADC_HC1; if neither is active the off condition is selected).

Note

Selecting more than one external hardware trigger select signal (ext_hwts[n]) prior to a conversion completion will generate unknown results. To avoid this, only select one hardware trigger select signal (ext_hwts[n]) prior to a conversion completion.

- Following the transfer of the result to the data registers when continuous conversion is enabled (ADCO=1 in ADC_GC register).

If continuous conversion is enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation (ADTRG=0), continuous conversions begin after ADC_HC1 is written and continue until aborted. In hardware triggered operation(ADTRG=1 and one external hardware trigger select event has occurred), continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions is completed. In software triggered operation, conversions begin after ADC_HC1 is written. In hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions is also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

37.8.5.2 Completing Conversions

A conversion is completed when the result of the conversion is transferred into the data result registers. (provided the compare function & hardware averaging is disabled), this is indicated by the setting of COCOn. If hardware averaging is enabled, COCOn sets only, if the last of the selected number of conversions is complete. If the compare function is enabled, COCOn sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then COCOn sets only if the last of the selected number of conversions is complete and the compare condition is true. An interrupt is generated, if ADC_HCn[AIEN] is high at the

time that COCOn is set and if DMAEN is set, DMA request is asserted, if COCOn is set. Both the requests get deasserted when COCOn is low, cleared, which happens when data is read.

In all modes a blocking mechanism prevents a new result from overwriting previous data in ADC_Rn, if the previous data is in the process of being read. When blocking is active (OVWREN=0 in ADC_CFG), the conversion result data transfer is blocked, COCOn is not set, and the new result is lost. In all other cases of operation, when a conversion result data transfer is blocked, another conversion is initiated regardless of the state of ADCO (single or continuous conversions enabled).

Note

If continuous conversions are enabled, the blocking mechanism could result in the loss of data occurring at specific timepoints. To avoid this issue, the data must be read in fewer cycles than an ADC conversion time, accounting for interrupt or software polling loop latency.

If single conversions are enabled, the blocking mechanism could result in several discarded conversions and excess power consumption. To avoid this issue, the data registers must not be read after initiating a single conversion until the conversion completes.

37.8.5.3 Aborting Conversions

Any conversion in progress is aborted when:

- The MCU enters stop mode with ADACK not enabled.
- In software trigger mode, write to ADC_HC0 register, while ADC_HC0 is actively (already) controlling a conversion, aborts the current conversion. Since, any of the ADC_HC1 - ADC_HCn registers are not used for software trigger operation therefore, write to any of them neither initiate a new conversion nor abort the software triggered active conversion.
- In hardware trigger mode, write to any one of the ADC_HC0 - ADC_HCn register, while that specific ADC_HC0 - ADC_HCn register is actively controlling a conversion, aborts the current conversion.
- A write to any ADC register besides the ADC_HC0: ADC_HCn registers occurs . This indicates a mode of operation change has occurred and the current conversion is therefore invalid.

Note

When a conversion is aborted, the contents of the data result registers, ADCRn are not altered. The data result registers continue to hold the values, transferred after the completion of the last successful conversion. If the conversion is aborted by a reset or stop (not operated with internal ADACK), ADCRn (data result register) return to their reset states.

37.8.5.4 Power Control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source but the asynchronous clock output is disabled (ADACKEN=0), the ADACK clock generator will also remain in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled (ADACKEN=1), it will remain active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting ADLPC..

37.8.5.5 Sample Time and Total Conversion Time

The total conversion time depends upon the following:

- the sample phase time (as determined by ADLSMP and ADSTS bits in ADC_CFG register),
- the compare phase time (determined by MODE bits)
- the frequency of the conversion clock (fADCK).
- the MCU bus frequency (for Handshaking and selection of clock)

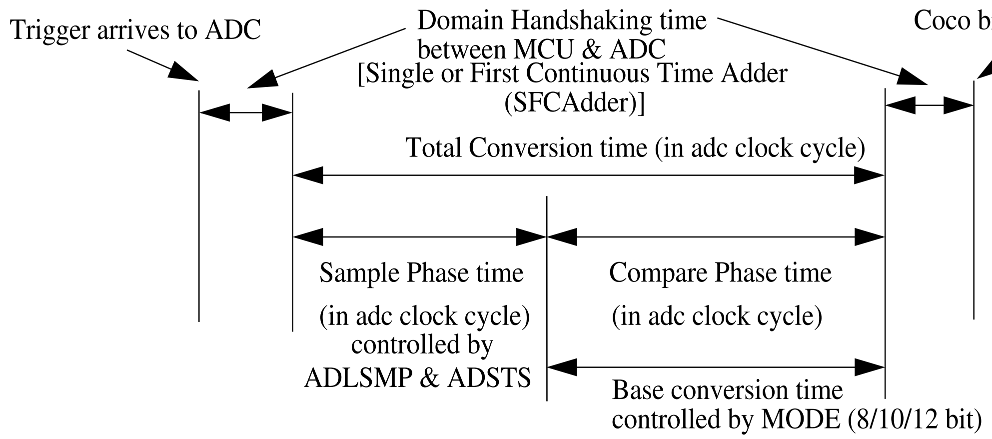

Figure 37-39. ADC conversion time details

After the module becomes active, sampling of the input begins. ADLSMP and ADSTS decide the sample time duration. When sampling is complete, the converter is isolated from the input channel and a successive approximation algorithm is performed to determine the digital value of the analog signal. The result of the conversion is transferred to ADC_Rn upon completion of the conversion algorithm.

If the bus frequency is less than the f_{ADCK} frequency, precise sample time for continuous conversions cannot be guaranteed .

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by the ADICLK bits in ADC_CFG register, and the divide ratio is specified by the ADIV bits.

The maximum total conversion time for all configurations is summarized in Figure 37-40. Refer to Table 37-46 through Table 37-49 for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder})$$

Figure 37-40.

Table 37-46. Single or First Continuous Time Adder (SFCAdder)

ADACKEN	ADICLK	Single or First Continuous Time Adder (SFCAdder)
x	0x, 10	3 ADCK cycles (before starting of conversion) + 1ADCK (after end of conversion) + 2 bus clock cycles

Table continues on the next page...

Table 37-46. Single or First Continuous Time Adder (SFCAdder) (continued)

ADACKEN	ADICLK	Single or First Continuous Time Adder (SFCAdder)
1	11	3 ADCK cycles (before starting of conversion) + 1 ADCK (after end of conversion) + 2 bus clock cycles
0	11	1.5µs + 3 ADCK cycles (before starting of conversion) + 1 ADCK (after end of conversion) + 2 bus clock cycles

Table 37-47. Average Number Factor (AverageNum)

AVGE	AVGS[1:0]	Average Number Factor (AverageNum)
0	xx	1
1	00	4
1	01	8
1	10	16
1	11	32

Table 37-48. Base Conversion Time (BCT) (compare phase duration)

Mode	Base Conversion Time (BCT) (compare phase duration)
8 bit	17 ADCK cycles
10 bit	21 ADCK cycles
12 bit	25 ADCK cycles

Table 37-49. Long Sample Time

ADLSMP	ADSTS	Long Sample Time Adder (LSTAdder)
0	00	3 ADCK cycles
0	01	5 ADCK cycles
0	10	7 ADCK cycles (default)
0	11	9 ADCK cycles
1	00	13 ADCK cycles
1	01	17 ADCK cycles

Table continues on the next page...

Table 37-49. Long Sample Time (continued)

ADLSMP	ADSTS	Long Sample Time Adder (LSTAdder)
1	10	21 ADCK cycles
1	11	25 ADCK cycles

Note

The ADCK frequency must be between f_{ADCK} minimum and f_{ADCK} maximum to meet ADC specifications.

37.8.5.6 Conversion Time Examples

The following examples uses Figure 37-40 and the information provided in tables Table 37-46 through Table 37-49.

37.8.5.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is: 10-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, ADLSMP=0,ADLSTS=10 and high speed conversion disabled. The conversion time for a single conversion is calculated by using Figure 37-40 and the information provided in Table 37-50 through Table 37-52. The table below list the variables of Figure 37-40.

Table 37-50. Typical Conversion Time

Variable	Time
SFCAdder	5 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	21 ADCK cycles
LSTAdder	7

The resulting conversion time is generated using the parameters listed in Table 37-50. So for Bus clock equal to 40 Mhz and ADCK equal to 40 Mhz the resulting conversion time is 0.95 us.

37.8.5.6.2 Long conversion time configuration

A configuration for long ADC conversion is: 12-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-8 ratio selected, and a bus frequency of 40 MHz, long sample time enabled (ADLSMP=1, ADSTS=11) and configured for

longest adder and high speed conversion disabled. Average enabled for 32 conversions (AVGE=1, AVGS=11). The conversion time for this conversion is calculated by using equation on Sample Time and Total Conversion Time and the information provided in Table 37-46 through Table 37-49. The table below lists the variables of equation.

Table 37-51. Typical Conversion Time

Variable	Time
SFCAdder	3 ADCK cycles + 5 bus clock cycles
AverageNum	32
BCT	25 ADCK cycles
LSTAdder	25 ADCK cycles

The resulting conversion time is generated using the parameters listed in Table 37-51. So for Bus clock equal to 40 Mhz and ADCK equal to 5 Mhz the resulting conversion time is 10.0226 us (AverageNum). This results in a total conversion time of 320.725 us.

37.8.5.6.3 Short conversion time configuration

A configuration for short ADC conversion is: 8-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, long sample time disabled(ADLSMP=0, ADSTS=00) and high speed conversion enabled. The conversion time for this conversion is calculated by using the equation and the information provided in Table 37-46 to Table 37-49. The table below list the variables of equation.

Table 37-52. Typical Conversion Time

Variable	Time
SFCAdder	3 ADCK cycles + 5 bus clock cycles
AverageNum	1
BCT	17 ADCK cycles
LSTAdder	3 ADCK cycles

The resulting conversion time is generated using the parameters listed in Table 37-52. So for Bus clock equal to 40Mhz and ADCK equal to 40Mhz the resulting conversion time is 700 ns.

37.8.5.7 Hardware Average Function

The hardware average function can be enabled (AVGE=1) to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which select 4, 8, 16 or 32 conversions to be averaged. While the hardware average function is in progress the ADACT bit will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated once the selected number of conversions has been completed. When hardware averaging is selected the completion of a single conversion will not set the COCOn bit.

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, ADC_Rn , and the COCOn bit is set. An ADC interrupt is generated upon the setting of COCOn if the respective ADC interrupt is enabled (AIENn=1).

37.8.6 Automatic Compare Function

The compare function can be configured to check if the result is less than or greater-than-or-equal-to a single compare value, or if the result falls within or outside a range determined by two compare values. The compare mode is determined by ACFGT, ACREN and the values in the compare value register (ADC_CV). After the input is sampled and converted, the compare values (CV1 and CV2) are used as described in the table below. There are six compare modes as shown in the table below.

Table 37-53. Compare Modes

ACFGT	ACREN	CV1 relative to CV2	Function	Compare Mode Description
0	0	-	Less than threshold	Compare true if the result is less than the CV1 registers.
1	0	-	Greater than or equal to threshold	Compare true if the result is greater than or equal to CV1 registers.
0	1	Less than or equal	Outside range, not inclusive	Compare true if the result is less than CV1 **Or** the result is Greater than CV2
0	1	Greater than	Inside range, not inclusive	Compare true if the result is less than CV1 **And** the result is greater than CV2
1	1	Less Than or equal	Inside range, inclusive	Compare true if the result is greater than or equal to CV1 **And** the result is less than or equal to CV2
1	1	Greater than	Outside range, inclusive	Compare true if the result is greater than or equal to CV1 **Or** the result is less than or equal to CV2

With the ADC range enable bit set, ADCREN =1, if compare value 1(CV1 value) is less than or equal to the compare value 2 (CV2 value), setting ACFGT will select a trigger-if-inside-compare-range, inclusive-of-endpoints function. Clearing ACFGT will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than the CV2, setting ACFGT will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing ACFGT will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, COCOn is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, COCOn is not set and the conversion result data will not be transferred to the result register. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated upon the setting of COCOn if the respective ADC interrupt is enabled (ADC_HCn[AIEN]=1).

Note

The compare function can monitor the voltage on a channel while the MCU is in wait or stop3 mode. The ADC interrupt wakes the MCU when the compare condition is met.

37.8.7 Calibration Function

The ADC contains a self-calibration function that is required to achieve the specified accuracy. Calibration should be run or valid calibration values should be written after power up and system reset (as the calibration register will be reset on reset assertion) with specified settings before any conversion is initiated. The calibration function sets the calibration value at the end of running the full calibration sequence in ADC_CAL register. The user must configure the ADC correctly prior to starting the calibration process, and must allow the process to run the full calibration sequence by checking the status of ADC_GC[CAL] and ADC_GS[CALF] so that the generated calibration value can be loaded.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, averaging, and the high speed configuration according to the application's clock source availability and needs. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. The input channel, conversion mode, continuous function and compare function are all ignored during the calibration process.

To initiate calibration, the user sets the CAL bit and the calibration will automatically begin if the ADTRG bit = 0. If ADTRG = 1, the CAL bit will not get set and the calibration fail flag (CALF) will be set. While calibration is active, no ADC register can be written and no stop mode may be entered or the calibration routine will be aborted causing the CAL bit to clear and the CALF bit to set.

At the end of a calibration sequence the COCO[0] bit of the ADC_HS register will be set. The ADC_HCn[AIEN] bit can be used to allow an interrupt to occur at the end of a calibration sequence. If, at the end of calibration routine, the CALF bit is not set, the automatic calibration routine completed successfully.

To complete calibration, the user must follow the below procedure :

- Configure ADC_CFG with actual operating values for maximum accuracy.
- Configure ADC_TEST register with all zero
- Configure the ADC_GC values along with CAL bit
- Check the status of CALF bit in ADC_GS and the CAL bit in ADC_GC
- When CAL bit becomes '0' then check the CALF status and COCO[0] bit status

When complete the user may reconfigure and use the ADC as desired.

A second calibration may also be performed if desired by clearing and again setting the CAL bit

Overall the calibration routine may take as many as 14000 ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen.

37.8.8 User Defined Offset Function

The ADC Offset Correction Register (ADC_OFS) contains the user configured offset value. This register is 13 bit wide. The value in MSB (13th bit) is the operation bit, if this bit is ‘0’ then the value in rest 12 bit is added with the converted result value to generate final result to be loaded into ADC_Rn and if this bit is ‘1’ then this field is subtracted from converted value to generate final Result (ADC_Rn). If the Final result is above the maximum or below the minimum result value, it is forced to the appropriate limit for the current mode of operation. Forced to 0x0FFF if over and 0x0000 if lower for 12 bit mode.

The offset value has no effect during calibration and BIST test on final result.

The formatting of the ADC Offset Register is different from the Data Result Registers (ADC_Rn) to preserve the resolution of the value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8b single-ended mode, the bits OFS[11:4] are subtracted from D[7:0] when bit OFS[12] (sign bit) is ‘1’ ; indicates subtraction and bits OFS[4:0] are ignored. For 12b single-ended mode, bits OFS[11:0] are directly subtracted from the conversion result data D[11:0] when OFS[12] (sign bit) is ‘1’. The similar is the addition operation when OFS[12](sign bit) is 0.

ADC_OFS is manually set according to user requirements once the self calibration sequence is done (CAL is cleared). The user have to write ADC_OFS with desired value.

NOTE

There is an effective limit to the values of Offset that can be set by the user. If the magnitude of the offset is too great the results of the conversions will cap off at the limits.

The offset function may be employed by the user to remove application offsets or DC bias values. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value.

For applications which may change the offset repeatedly during operation, it is recommended to store the initial offset value in flash so that it can be recovered and added to any user offset adjustment value and the sum stored in the ADC_OFS registers.

37.8.9 Temperature Sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs (ADC_HCn[AIEN] = 011010 = 26). This channel can be selected through configuring the ADCHn bits of any ADC_HCn register. Any trigger on this will give a temperature value converted for further processings.

Figure 37-40 provides an approximate transfer function of the temperature sensor .

$$\mathrm{Temp} = 25 - \left(\left(V_{\mathrm{TEMP}} - V_{\mathrm{TEMP25}}\right) \div m\right)$$

where:

- V_{TEMP} is the voltage of the temperature sensor channel at the ambient temperature.
- V_{TEMP25} is the voltage of the temperature sensor channel at 25°C.
- m is the hot or cold voltage versus temperature slope in V/°C.

For temperature calculations, use the V_{TEMP25} and m values from the ADC Electricals table.

In application code, the user reads the temperature sensor channel, calculates V_{TEMP}, and compares to V_{TEMP25}. If V_{TEMP} is greater than V_{TEMP25} the cold slope value is applied in Figure 37-40. If V_{TEMP} is less than V_{TEMP25} the hot slope value is applied in Figure 37-40.

For more information on using the temperature sensor, consult AN3031.

37.8.10 MCU Wait Mode Operation

Wait mode is a **lower power-consumption standby mode** from which **recovery is fast** because **the clock sources remain active**. If a conversion is in progress when the MCU enters wait mode, it continues until completion. Conversions can be initiated while the MCU is in wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two, and ADACK are available as conversion clock sources while in wait mode. The use of ALTCLK as the conversion clock source in wait is dependent on the definition of ALTCLK for the specific MCU.

A conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from wait mode.

If the compare and hardware averaging functions are disabled, a conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from wait mode if the respective ADC interrupt is enabled (ADC_HCn[AIEN]=1).

If the hardware averaging function is enabled the COCOn will set (and generate an interrupt if enabled) when the selected number of conversions are complete.

If the compare function is enabled the COCOn will set (and generate an interrupt if enabled) only if the compare conditions are met.

If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from wait mode unless a new conversion is initiated by the hardware trigger.

37.8.11 MCU Stop Mode Operation

Stop mode is a low power-consumption standby mode during which most or all clock sources on the MCU are disabled. Stop mode entered when stop indication comes from the MCU.

37.8.11.1 Stop Mode With ADACK Disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its idle state. The contents of the ADC registers, including ADC_Rn are unaffected by stop mode. After exiting from stop mode, a software or hardware trigger is required to resume conversions.

37.8.11.2 Stop Mode With ADACK Enabled

If ADACK is selected as the conversion clock, the ADC continues operation during stop mode. For guaranteed ADC operation, the MCU's voltage regulator must remain active during stop mode.

If a conversion is in progress when the MCU enters stop mode, it continues until completion. Conversions can be initiated while the MCU is in stop mode by means of the hardware trigger or if continuous conversions are enabled.

A conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from stop mode :

Note

The ADC module can wake the system from low-power stop and cause the MCU to begin consuming run-level currents without generating a system level interrupt. To prevent this scenario, software should ensure the conversion result data transfer blocking mechanism (discussed in Completing Conversions) is cleared when entering stop and continuing ADC conversions.

37.9 Initialization Information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. User can configure the module for 8, 10, 12 bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options.

37.9.1 ADC Module Initialization Example

This section describes the initialization sequence along with pseudo-code.

37.9.1.1 Initialization Sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is as follows:

- Calibrate the ADC by following the calibration instructions in Calibration Function
- Update the configuration register (ADC_CFG) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
- Update Genral control register (ADC_GC) to select whether conversions will be continuous or completed only once (ADCO) and to select whether to perform hardware averaging, etc.
- Update Trigger control register (ADC_HCn) to select the conversion trigger (hardware or software, i.e. configure ADTRG bit) and compare function options, if enabled.

37.9.1.2 Pseudo-Code Example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

ADC_CFG

```
Bit 7    ADLPC    1      Configures for low power (lowers maximum clock speed.
```

```
Bit 6:5  ADIV    00     Sets the ADCK to the input clock  ÷  1.
Bit 4    ADLSMP  1      Configures for long sample time.
Bit 3:2  MODE    10     Sets mode at 10-bit conversions.
Bit 1:0  ADICLK  00     Selects bus clock as input clock source.
```

ADC_GC

```
Bit 7    CAL     0      Flag indicates if a conversion is in progress.
Bit 6    ADCO    0      Software trigger selected.
Bit 5    AVGE    0      Compare function disabled.
Bit 4    ACFE    0      Compare function disabled.
Bit 3    ACFGT   0      Not used in this example.
Bit 2    ACREN   0      Not used in this example.
Bit 1    DMAEN   0      Not used in this example.
Bit 0    ADACKEN 0      Not used in this example.
```

ADC_HC0

```
   Bit 7    AIEN   1      Conversion complete interrupt enabled.
Bit 4:0  ADCH   00001  Input channel 1 selected as ADC input channel.
```

ADC_R0

Holds results of conversion. Read high byte (ADCRHA) before low byte (ADCRLA) so that conversion data cannot be overwritten with data from the next conversion.

ADC_CV

Holds compare values when compare function enabled.

ADC_PCTL

AD1 pin I/O control disabled. All other AD pins remain general purpose I/O pins.

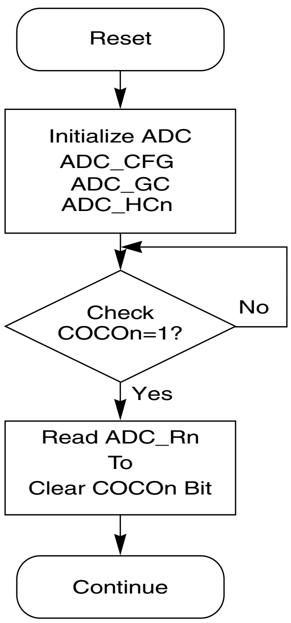

Figure 37-41. Initialization Flowchart for Example

37.10 Application Information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

37.10.1 Sources of Error

Several sources of error exist for A/D conversions. These are discussed in the following sections.

37.10.1.1 Sampling Error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Given the maximum input resistance of approximately 7kΩ and input capacitance of approximately 1.3 pF, sampling to within 1/4LSB (at 12-bit resolution) can be achieved within the nominal sample window (6 cycles @ 40 MHz maximum ADCK frequency) provided the resistance of the external analog source (R_{AS}) is kept below 4 kΩ.

Higher source resistances or higher-accuracy sampling is possible by setting ADLSMP and changing the ADSTS bits (to increase the sample window) or decreasing ADCK frequency to increase sample time.

37.10.1.2 Pin Leakage Error

Leakage on the I/O pins can cause conversion error if the external analog source resistance (R_{AS}) is high. If this error cannot be tolerated by the application, keep R_{AS} lower than V_{DDAD} / (2^N*I_{LEAK}) for less than 1/4LSB leakage error (N = 8 in 8-bit, 10 in 10-bit or 12 in 12-bit mode).

37.10.1.3 Noise-Induced Errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1 μF low-ESR capacitor from V_{REFH} to V_{REFL}.
- There is a 0.1 μF low-ESR capacitor from V_{DDAD} to V_{SSAD}.
- If inductive isolation is used from the primary supply, an additional 1 μF capacitor is placed from V_{DDAD} to V_{SSAD}.
- V_{SSAD} (and V_{REFL}, if connected) is connected to V_{SS} at a quiet point in the ground plane.
- Operate the MCU in wait or stop mode before initiating (hardware triggered conversions) or immediately after initiating (hardware or software triggered conversions) the ADC conversion.
  - For software triggered conversions, immediately follow the write to ADCSC1 with a wait instruction or stop instruction.
  - For stop mode operation, select ADACK as the clock source. Operation in stop reduces V_{DD} noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive V_{DD} noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in wait or stop or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:

- Place a 0.01 μF capacitor (CAS) on the selected input channel to V_{REFL} or V_{SSAD} (this improves noise issues, but affects the sample rate based on the external analog source resistance).
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock (ADACK) and averaging. Noise that is synchronous to ADCK cannot be averaged out.

37.10.1.4 Code Width and Quantization Error

Note

This will remain the same as long as the result is rounded for 8 and 10-bit modes. If the result is truncated in 8/10b modes then they will match 12b mode where the quantization error is -1 to 0

The ADC quantizes the ideal straight-line transfer function into 4096 steps (in 12-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 8, 10 or 12), defined as 1LSB, is:

$$1\text{lsb} = (V_{\text{REFH}} - V_{\text{REFL}}) / 2^N$$

There is an inherent quantization error due to the digitization of the result. For 8-bit or 10-bit conversions the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be ± 1/2 lsb in 8- or 10-bit mode. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 lsb and the code width of the last (0xFF or 0x3FF) is 1.5 lsb.

For 12-bit conversions the code transitions only after the full code width is present, so the quantization error is -1 lsb to 0 lsb and the code width of each step is 1 lsb.

37.10.1.5 Linearity Errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system should be aware of them because they affect overall accuracy. These errors are:

- Zero-scale error (E_{ZS}) (sometimes called offset) — This error is defined as the difference between the actual code width of the first conversion and the ideal code width (1/2 lsb in 8-bit or 10-bit modes and 1 lsb in 12-bit mode). If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 lsb) is used.
- Full-scale error (E_{FS}) — This error is defined as the difference between the actual code width of the last conversion and the ideal code width (1.5 lsb in 8-bit or 10-bit modes and 1LSB in 12-bit mode). If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1LSB) is used.

- Differential non-linearity (DNL) — This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL) — This error is defined as the highest-value the (absolute value of the) running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE) — This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

37.10.1.6 Code Jitter, Non-Monotonicity, and Missing Codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes.

Code jitter is when, at certain points, a given input voltage converts to one of two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code (and vice-versa). However, even small amounts of system noise can cause the converter to be indeterminate (between two codes) for a range of input voltages around the transition voltage. This range is normally around ±1/2 lsb in 8-bit or 10-bit mode, or around 2 lsb in 12-bit mode, and increases with noise.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally the techniques discussed in Noise-Induced Errors reduces this error.

Non-monotonicity is defined as when, except for code jitter, the converter converts to a lower code for a higher input voltage. Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

Chapter 38
Programmable Delay Block (PDB)

38.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The Programmable Delay Block (PDB) provides controllable delays from either an internal or an external trigger, or a programmable interval tick, to the hardware trigger inputs of ADCs and/or generates the interval triggers to DACs, so that the precise timing between ADC conversions and/or DAC updates can be achieved.

38.1.1 Features

- Up to 15 trigger input sources and one software trigger source
- Up to eight configurable PDB channels for ADC hardware trigger
    - One PDB channel is associated with one ADC
    - One trigger output for ADC hardware trigger and up to eight pre-trigger outputs for ADC trigger select per PDB channel
    - Trigger outputs can be enabled or disabled independently
    - One 16-bit delay register per pre-trigger output
    - Optional bypass of the delay registers of the pre-trigger outputs
    - Operation in One-Shot or Continuous modes
    - Optional back-to-back mode operation, which enables the ADC conversions complete to trigger the next PDB channel

  - One programmable delay interrupt
  - One sequence error interrupt
  - One channel flag and one sequence error flag per pre-trigger
  - DMA support
- Up to eight DAC interval triggers
  - One interval trigger output per DAC
  - One 16-bit delay interval register per DAC trigger output
  - Optional bypass of the delay interval trigger registers
  - Optional external triggers
- Up to eight pulse outputs (pulse-out's)
  - Pulse-out's can be enabled or disabled independently
  - Programmable pulse width

NOTE

The number of PDB input and output triggers are chip-specific. See the chip configuration information for details.

38.1.2 Implementation

In this section, the following letters refer to the number of output triggers:

- N—Total available number of PDB channels.
- n—PDB channel number, valid from 0 to N-1.
- M—Total available pre-trigger per PDB channel.
- m—Pre-trigger number, valid from 0 to M-1.
- X—Total number of DAC interval triggers.
- x—DAC interval trigger output number, valid from 0 to X-1.
- Y—Total number of Pulse-Out's.
- y—Pulse-Out number, valid value is from 0 to Y-1.

NOTE

The number of module output triggers to core is chip-specific. For module to core output triggers implementation, see the chip configuration information.

38.1.3 Back-to-back acknowledgment connections

PDB back-to-back operation acknowledgment connections are chip-specific. For implementation, see the chip configuration information.

38.1.4 Block diagram

This diagram illustrates the major components of the PDB.

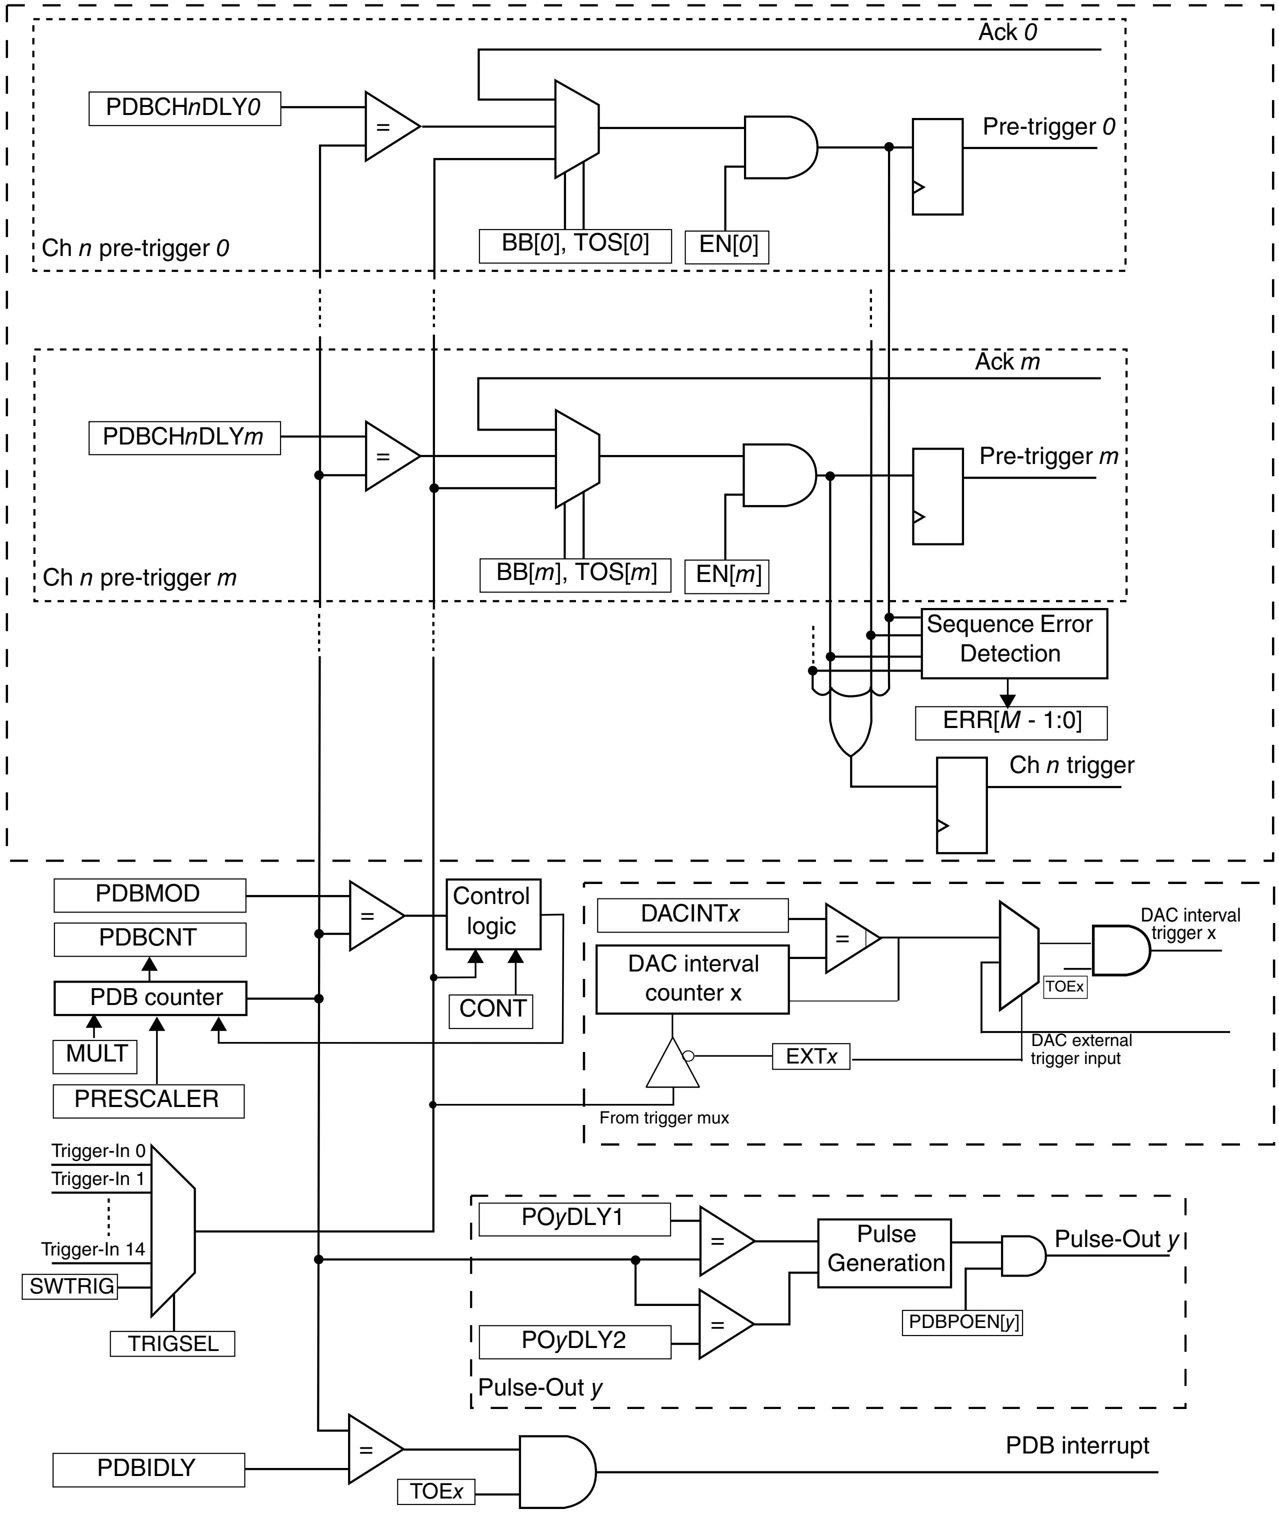

Figure 38-1. PDB block diagram

In this diagram, only one PDB channel *n*, one DAC interval trigger *x*, and one Pulse-Out *y* are shown. The PDB-enabled control logic and the sequence error interrupt logic are not shown.

38.1.5 Modes of operation

PDB ADC trigger operates in the following modes:

- Disabled—Counter is off, all pre-trigger and trigger outputs are low if PDB is not in back-to-back operation of Bypass mode.
- Debug—Counter is paused when processor is in Debug mode, and the counter for the DAC trigger is also paused in Debug mode.
- Enabled One-Shot—Counter is enabled and restarted at count zero upon receiving a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1. In each PDB channel, an enabled pre-trigger asserts once per trigger input event. The trigger output asserts whenever any of the pre-triggers is asserted.
- Enabled Continuous—Counter is enabled and restarted at count zero. The counter is rolled over to zero again when the count reaches the value specified in the modulus register, and the counting is restarted. This enables a continuous stream of pre-triggers/trigger outputs as a result of a single trigger input event.
- Enabled Bypassed—The pre-trigger and trigger outputs assert immediately after a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1, that is the delay registers are bypassed. It is possible to bypass any one or more of the delay registers; therefore, this mode can be used in conjunction with One-Shot or Continuous mode.

38.2 PDB signal descriptions

This table shows the detailed description of the external signal.

Table 38-1. PDB signal descriptions

Signal	Description	I/O
EXTRG	External Trigger Input Source If the PDB is enabled and external trigger input source is selected, a positive edge on the EXTRG signal resets and starts the counter.	I

38.3 Memory map and register definition

PDB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

PDB_SC field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–18 LDMOD	Load Mode Select Selects the mode to load the MOD, IDLY, CH*n*DLY*m*, INT*x*, and PO*y*DLY registers, after 1 is written to LDOK. 00 The internal registers are loaded with the values from their buffers immediately after 1 is written to LDOK. 01 The internal registers are loaded with the values from their buffers when the PDB counter reaches the MOD register value after 1 is written to LDOK. 10 The internal registers are loaded with the values from their buffers when a trigger input event is detected after 1 is written to LDOK. 11 The internal registers are loaded with the values from their buffers when either the PDB counter reaches the MOD register value or a trigger input event is detected, after 1 is written to LDOK.
17 PDBEIE	PDB Sequence Error Interrupt Enable Enables the PDB sequence error interrupt. When this field is set, any of the PDB channel sequence error flags generates a PDB sequence error interrupt.

Table continues on the next page...

PDB_SC field descriptions (continued)

Field	Description
	0 PDB sequence error interrupt disabled. 1 PDB sequence error interrupt enabled.
16 SWTRIG	Software Trigger When PDB is enabled and the software trigger is selected as the trigger input source, writing 1 to this field resets and restarts the counter. Writing 0 to this field has no effect. Reading this field results 0.
15 DMAEN	DMA Enable When DMA is enabled, the PDBIF flag generates a DMA request instead of an interrupt. 0 DMA disabled. 1 DMA enabled.
14–12 PRESCALER	Prescaler Divider Select 000 Counting uses the peripheral clock divided by multiplication factor selected by MULT. 001 Counting uses the peripheral clock divided by twice of the multiplication factor selected by MULT. 010 Counting uses the peripheral clock divided by four times of the multiplication factor selected by MULT. 011 Counting uses the peripheral clock divided by eight times of the multiplication factor selected by MULT. 100 Counting uses the peripheral clock divided by 16 times of the multiplication factor selected by MULT. 101 Counting uses the peripheral clock divided by 32 times of the multiplication factor selected by MULT. 110 Counting uses the peripheral clock divided by 64 times of the multiplication factor selected by MULT. 111 Counting uses the peripheral clock divided by 128 times of the multiplication factor selected by MULT.
11–8 TRGSEL	Trigger Input Source Select Selects the trigger input source for the PDB. The trigger input source can be internal or external (EXTRG pin), or the software trigger. Please refer to Chip Configuration chapter for the actual PDB input trigger connections. 0000 Trigger-In 0 is selected. 0001 Trigger-In 1 is selected. 0010 Trigger-In 2 is selected. 0011 Trigger-In 3 is selected. 0100 Trigger-In 4 is selected. 0101 Trigger-In 5 is selected. 0110 Trigger-In 6 is selected. 0111 Trigger-In 7 is selected. 1000 Trigger-In 8 is selected. 1001 Trigger-In 9 is selected. 1010 Trigger-In 10 is selected. 1011 Trigger-In 11 is selected. 1100 Trigger-In 12 is selected. 1101 Trigger-In 13 is selected. 1110 Trigger-In 14 is selected. 1111 Software trigger is selected.

Table continues on the next page...

PDB_SC field descriptions (continued)

Field	Description
7 PDBEN	PDB Enable 0 PDB disabled. Counter is off. 1 PDB enabled.
6 PDBIF	PDB Interrupt Flag This field is set when the counter value is equal to the IDLY register. Writing zero clears this field.
5 PDBIE	PDB Interrupt Enable Enables the PDB interrupt. When this field is set and DMAEN is cleared, PDBIF generates a PDB interrupt. 0 PDB interrupt disabled. 1 PDB interrupt enabled.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 MULT	Multiplication Factor Select for Prescaler Selects the multiplication factor of the prescaler divider for the counter clock. 00 Multiplication factor is 1. 01 Multiplication factor is 10. 10 Multiplication factor is 20. 11 Multiplication factor is 40.
1 CONT	Continuous Mode Enable Enables the PDB operation in Continuous mode. 0 PDB operation in One-Shot mode 1 PDB operation in Continuous mode
0 LDOK	Load OK Writing 1 to this bit updates the internal registers of MOD, IDLY, CHnDLYm, DACINTx,and POyDLY with the values written to their buffers. The MOD, IDLY, CHnDLYm, DACINTx, and POyDLY will take effect according to the LDMOD. After 1 is written to the LDOK field, the values in the buffers of above registers are not effective and the buffers cannot be written until the values in buffers are loaded into their internal registers. LDOK can be written only when PDBEN is set or it can be written at the same time with PDBEN being written to 1. It is automatically cleared when the values in buffers are loaded into the internal registers or the PDBEN is cleared. Writing 0 to it has no effect.

38.3.2 Modulus register (PDB_MOD)

Address: 4003_6000h base + 4h offset = 4003_6004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PDB_CH*n*C1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 BB	PDB Channel Pre-Trigger Back-to-Back Operation Enable These bits enable the PDB ADC pre-trigger operation as back-to-back mode. Only lower M pre-trigger bits are implemented in this MCU. Back-to-back operation enables the ADC conversions complete to trigger the next PDB channel pre-trigger and trigger output, so that the ADC conversions can be triggered on next set of configuration and results registers. Application code must only enable the back-to-back operation of the PDB pre-triggers at the leading of the back-to-back connection chain. 0 PDB channel's corresponding pre-trigger back-to-back operation disabled. 1 PDB channel's corresponding pre-trigger back-to-back operation enabled.
15–8 TOS	PDB Channel Pre-Trigger Output Select Selects the PDB ADC pre-trigger outputs. Only lower M pre-trigger fields are implemented in this MCU. 0 PDB channel's corresponding pre-trigger is in bypassed mode. The pre-trigger asserts one peripheral clock cycle after a rising edge is detected on selected trigger input source or software trigger is selected and SWTRIG is written with 1. 1 PDB channel's corresponding pre-trigger asserts when the counter reaches the channel delay register and one peripheral clock cycle after a rising edge is detected on selected trigger input source or software trigger is selected and SETRIG is written with 1.
7–0 EN	PDB Channel Pre-Trigger Enable These bits enable the PDB ADC pre-trigger outputs. Only lower M pre-trigger bits are implemented in this MCU. 0 PDB channel's corresponding pre-trigger disabled. 1 PDB channel's corresponding pre-trigger enabled.

38.3.6 Channel n Status register (PDB_CH*n*S)

Address: 4003_6000h base + 14h offset + (40d × i), where i=0d to 1d

Bit	31–24	23–16	15–8	7–0

PDB_DACINTn field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 INT	DAC Interval Specifies the interval value for DAC interval trigger. DAC interval trigger triggers DAC[1:0] update when the DAC interval counter is equal to the DACINT. Reading this field returns the value of internal register that is effective for the current PDB cycle.

38.4 Functional description

38.4.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared against several different digital values. If the PDB is enabled, a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on selected trigger input source or software trigger being selected and SC[SWTRIG] is written with 1. For each channel, delay *m* determines the time between assertion of the trigger input event to the point at which changes in the pre-trigger *m* output signal is initiated. The time is defined as:

- Trigger input event to pre-trigger *m* = (prescaler X multiplication factor X delay *m*) + 2 peripheral clock cycles
- Add one additional peripheral clock cycle to determine the time at which the channel trigger output change.

Each channel is associated with one ADC block. PDB channel n pre-trigger outputs 0 to *M* and trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block prior to the actual trigger. The ADC contains *M* sets of configuration and result registers, allowing it to operate in a ping-pong fashion, alternating conversions between *M* different analog sources. The pre-trigger outputs are used to specify which signal will be sampled next. When pre-trigger *m* is asserted, the ADC conversion is triggered with set *m* of the configuration and result registers.

The waveforms shown in the following diagram illustrate the pre-trigger and trigger outputs of PDB channel *n*. The delays can be independently set via the CH*n*DLY*m* registers. And the pre-triggers can be enabled or disabled in CH*n*C1[EN[*m*]].

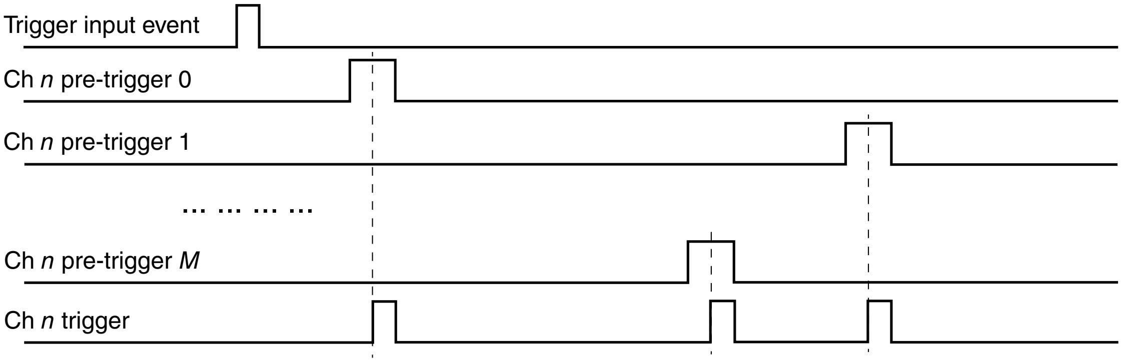

Figure 38-24. Pre-trigger and trigger outputs

The delay in CH*n*DLY*m* register can be optionally bypassed, if CH*n*C1[TOS[*m*]] is cleared. In this case, when the trigger input event occurs, the pre-trigger *m* is asserted after two peripheral clock cycles.

The PDB can be configured in back-to-back operation. Back-to-back operation enables the ADC conversions complete to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on the next set of configuration and results registers. When back-to-back is enabled by setting CH*n*C1[BB[*m*]], the delay *m* is ignored and the pre-trigger *m* is asserted two peripheral cycles after the acknowledgment *m* is received. The acknowledgment connections in this MCU is described in Back-to-back acknowledgment connections.

When an ADC conversion, which is triggered by one of the pre-triggers from PDB channel *n*, is in progress and ADC*n*SC1[COCO] is not set, a new trigger from PDB channel *n* pre-trigger *m* cannot be accepted by ADC*n*. Therefore every time when one PDB channel *n* pre-trigger and trigger output starts an ADC conversion, an internal lock associated with the corresponding pre-trigger is activated. This lock becomes inactive when:

- the corresponding ADC*n*SC1[COCO] is set
- the corresponding PDB pre-trigger is disabled, or
- the PDB is disabled

The channel *n* trigger output is suppressed when any of the locks of the pre-triggers in channel *n* is active. If a new pre-trigger *m* asserts when there is active lock in the PDB channel *n*, a register flag bit, CH*n*S[ERR[*m*]], associated with the pre-trigger *m* is set. If SC[PDBEIE] is set, the sequence error interrupt is generated. Sequence error typically happens because the delay *m* is set too short and the pre-trigger *m* asserts before the previously triggered ADC conversion is completed.

When the PDB counter reaches the value set in IDLY register, the SC[PDBIF] flag is set. A PDB interrupt can be generated if SC[PDBIE] is set and SC[DMAEN] is cleared. If SC[DMAEN] is set, PDB requests a DMA transfer when SC[PDBIF] is set.

The modulus value in the MOD register is used to reset the counter back to zero at the end of the count. If SC[CONT] is set, the counter will then resume a new count. Otherwise, the counter operation will cease until the next trigger input event occurs.

38.4.2 PDB trigger input source selection

The PDB has up to 15 trigger input sources, namely Trigger-In 14. They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through SC[SWTRIG]. SC[TRIGSEL] selects the active trigger input source or software trigger.

For the trigger input sources implemented in this MCU, see chip configuration information.

38.4.3 DAC interval trigger outputs

PDB can generate the interval triggers for DACs to update their outputs periodically. DAC interval counter *x* is reset and started when a trigger input event occurs if DACINTC*x*[EXT] is cleared. When the interval counter *x* is equal to the value set in DACINT*x* register, the DAC interval trigger *x* output generates a pulse of one peripheral clock cycle width to update the DAC*x*. If DACINTC*x*[EXT] is set, the DAC interval

counter is bypassed and the interval trigger output *x* generates a pulse following the detection of a rising edge on the DAC external trigger input. The counter and interval trigger can be disabled by clearing the DACINTC*x*[TOE].

DAC interval counters are also reset when the PDB counter reaches the MOD register value; therefore, when the PDB counter rolls over to zero, the DAC interval counters starts anew.

The DAC interval trigger pulse and the ADC pre-trigger/trigger pulses together allow precise timing of DAC updates and ADC measurements. This is outlined in the typical use case described in the following diagram.

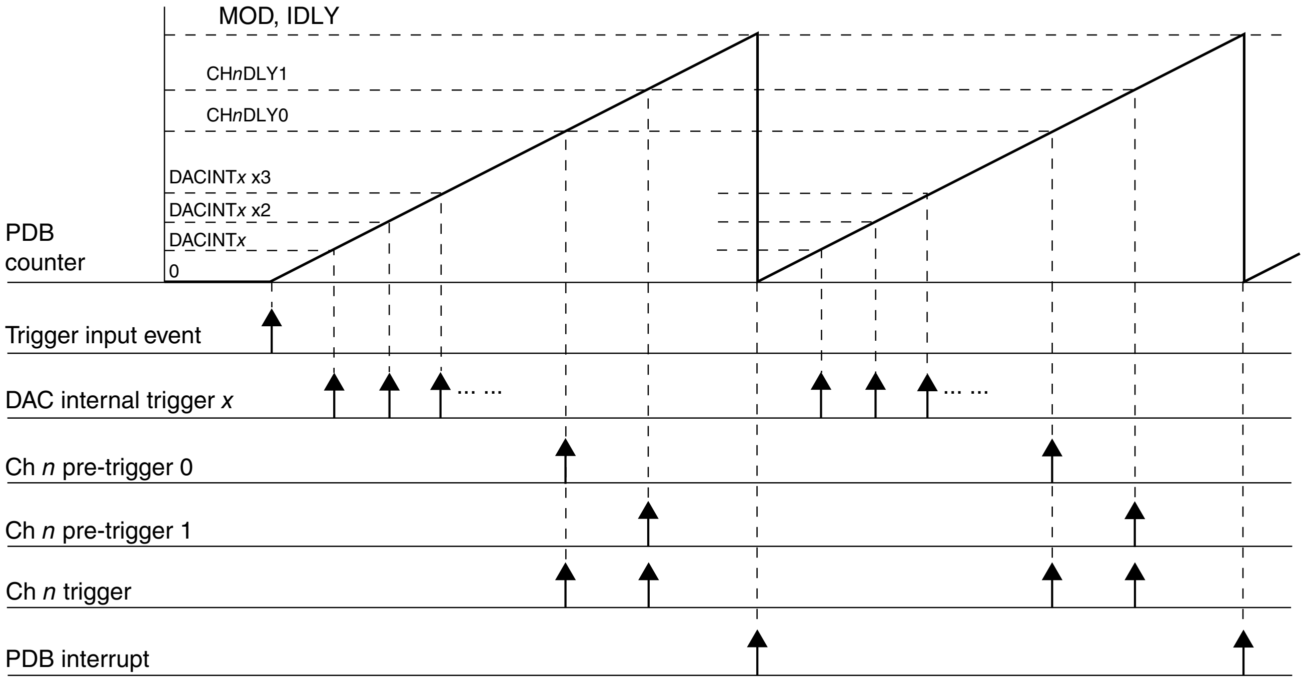

Figure 38-25. PDB ADC triggers and DAC interval triggers use case

NOTE

Because the DAC interval counters share the prescaler with PDB counter, PDB must be enabled if the DAC interval trigger outputs are used in the applications.

38.4.4 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus register (MOD)

- PDB Interrupt Delay register (IDLY)
- PDB Channel *n* Delay *m* register (CH*n*DLY*m*)
- DAC Interval *x* register (DACINT*x*)
- PDB Pulse-Out *y* Delay register (PO*y*DLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized as shown in the table below.

Table 38-25. Circumstances of update to the delay registers

SC[LDMOD]	Update to the delay registers
00	The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].
01	The PDB counter reaches the MOD register value after 1 is written to SC[LDOK].
10	A trigger input event is detected after 1 is written to SC[LDOK].
11	Either the PDB counter reaches the MOD register value, or a trigger input event is detected, after 1 is written to SC[LDOK].

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

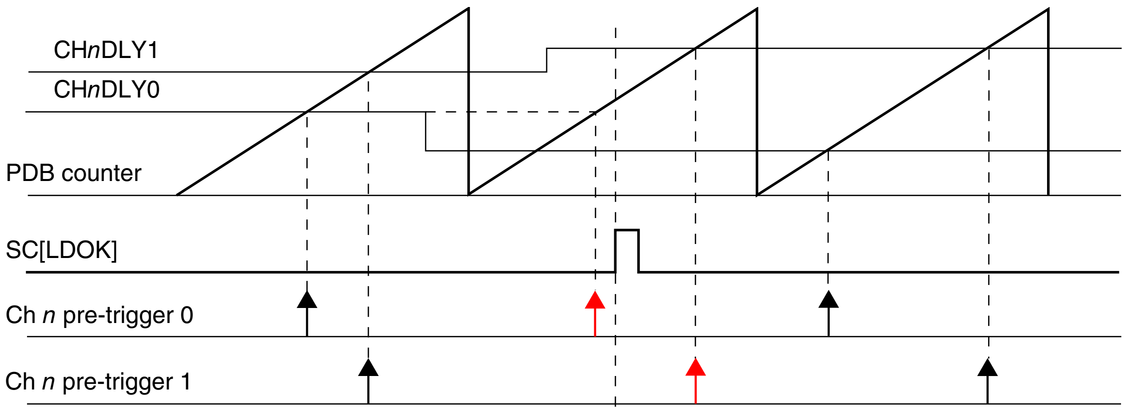

Figure 38-26. Registers update with SC[LDMOD] = 00

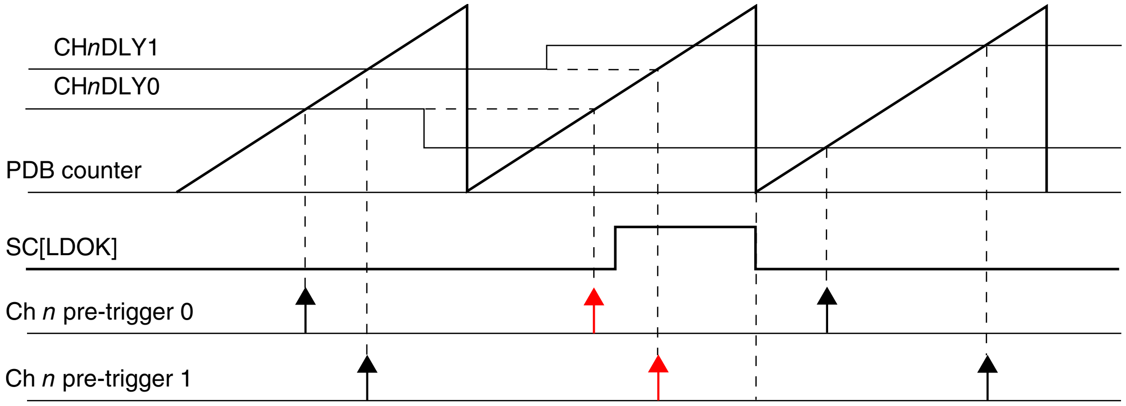

Figure 38-27. Registers update with SC[LDMOD] = x1

38.4.5 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

Table 38-26. PDB interrupt summary

Interrupt	Flags	Enable bit
PDB Interrupt	SC[PDBIF]	SC[PDBIE] = 1 and SC[DMAEN] = 0
PDB Sequence Error Interrupt	CH*n*S[ERR*m*]	SC[PDBEIE] = 1

38.4.6 DMA

If SC[DMAEN] is set, PDB can generate a DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt is not issued.

38.5 Application information

38.5.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only

values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use a prescaler set to 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

Chapter 39
FlexTimer Module (FTM)

39.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

39.1.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the HCS08 Timer PWM Module – TPM, used for many years on Freescale's 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Fault control inputs
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, fault control, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

Several FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

39.1.2 Features

The FTM features include:

- FTM source clock is selectable
    - Source clock can be the system clock, the fixed frequency clock, or an external clock
    - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
    - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter
    - It can be a free-running counter or a counter with initial and final value
    - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:

  - The capture can occur on rising edges, falling edges or both edges
  - An input filter can be selected for some channels
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Software control of PWM outputs
- Up to 4 fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

39.1.3 Modes of operation

When the MCU is in an active BDM mode, the FTM temporarily suspends all counting until the MCU returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a

real time reference or provide the interrupt sources needed to wake the MCU from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

39.1.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CHn (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

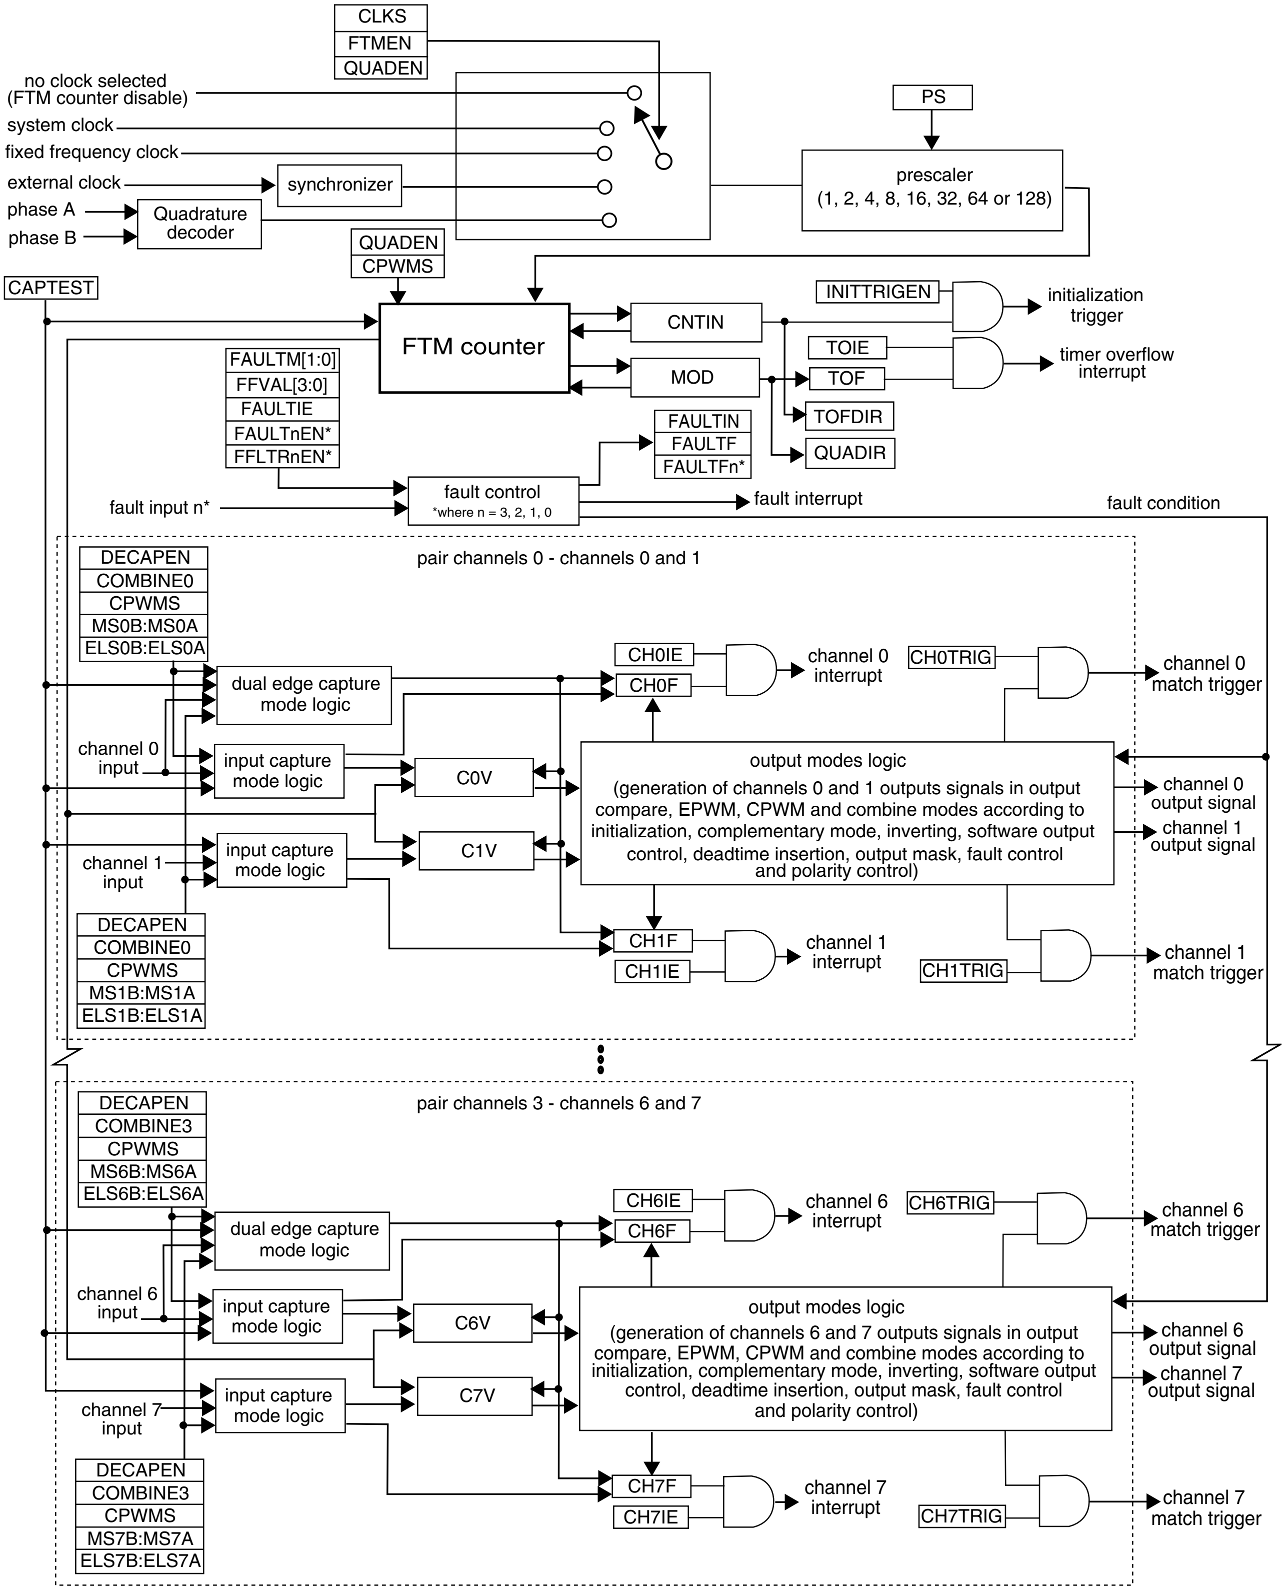

Figure 39-1. FTM block diagram

39.2 FTM signal descriptions

Table 39-1 shows the user-accessible signals for the FTM.

Table 39-1. FTM signal descriptions

Signal	Description	I/O	Function
EXTCLK	External clock. FTM external clock can be selected to drive the FTM counter.	I	The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.
CHn	FTM channel (n), where n can be 7-0	I/O	Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.
FAULTj	Fault input (j), where j can be 3-0	I	The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINEm register. Note that each FAULTj input may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Because there are several FAULTj inputs, maximum of 4 for the FTM module, each one of these inputs is activated by the FAULTjEN bit in the FLTCTRL register.
PHA	Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A.	I	The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder mode.
PHB	Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B.	I	The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder mode.

39.3 Memory map and register definition

39.3.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

Note

Do not write in the region from the CNTIN register through the PWMLOAD register when FTMEN = 0.

39.3.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

39.3.3 Status And Control (FTMx_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

Address: Base address + 0h offset

FTMx_SC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TOF	Timer Overflow Flag Set by hardware when the FTM counter passes the value in the MOD register. The TOF bit is cleared by reading the SC register while TOF is set and then writing a 0 to TOF bit. Writing a 1 to TOF has no effect. If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case, a TOF interrupt request is not lost due to the clearing sequence for a previous TOF. 0 FTM counter has not overflowed. 1 FTM counter has overflowed.

Table continues on the next page...

FTMx_SC field descriptions (continued)

Field	Description
6 TOIE	Timer Overflow Interrupt Enable Enables FTM overflow interrupts. 0 Disable TOF interrupts. Use software polling. 1 Enable TOF interrupts. An interrupt is generated when TOF equals one.
5 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the FTM to operate in Up-Down Counting mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 FTM counter operates in Up Counting mode. 1 FTM counter operates in Up-Down Counting mode.
4–3 CLKS	Clock Source Selection Selects one of the three FTM counter clock sources. This field is write protected. It can be written only when MODE[WPDIS] = 1. 00 No clock selected. This in effect disables the FTM counter. 01 System clock 10 Fixed frequency clock 11 External clock
2–0 PS	Prescale Factor Selection Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits. This field is write protected. It can be written only when MODE[WPDIS] = 1. 000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128

39.3.4 Counter (FTMx_CNT)

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–0 COUNT	Counter Value

39.3.5 Modulo (FTMx_MOD)

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see Counter.

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to Registers updated from write buffers.

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset

2 ELSA	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. See Table 39-7. This field is write protected. It can be written only when MODE[WPDIS] = 1.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 DMA	DMA Enable Enables DMA transfers for the channel. 0 Disable DMA transfers. 1 Enable DMA transfers.

39.3.7 Channel (n) Value (FTMx_C*n*V)

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to Registers updated from write buffers.

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–0 VAL	Channel Value Captured FTM counter value of the input modes or the match value for the output modes

39.3.8 Counter Initial Value (FTMx_CNTIN)

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to Registers updated from write buffers.

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FTMx_CNTIN field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–0 INIT	Initial Value Of The FTM Counter

39.3.9 Capture And Compare Status (FTMx_STATUS)

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

NOTE

The STATUS register should be used only in Combine mode.

Address: Base address + 50h offset

39.3.10 Features Mode Selection (FTMx_MODE)

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Fault control mode and interrupt
- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

Address: Base address + 54h offset

FTMx_MODE field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 FAULTIE	Fault Interrupt Enable Enables the generation of an interrupt when a fault is detected by FTM and the FTM fault control is enabled. 0 Fault control interrupt is disabled. 1 Fault control interrupt is enabled.
6–5 FAULTM	Fault Control Mode Defines the FTM fault control mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 00 Fault control is disabled for all channels. 01 Fault control is enabled for even channels only (channels 0, 2, 4, and 6), and the selected mode is the manual fault clearing. 10 Fault control is enabled for all channels, and the selected mode is the manual fault clearing. 11 Fault control is enabled for all channels, and the selected mode is the automatic fault clearing.
4 CAPTEST	Capture Test Mode Enable Enables the capture test mode. This field is write protected. It can be written only when MODE[WPDIS] = 1.

Table continues on the next page...

FTMx_MODE field descriptions (continued)

Field	Description
	0 Capture test mode is disabled. 1 Capture test mode is enabled.
3 PWMSYNC	PWM Synchronization Mode Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See PWM synchronization. The PWMSYNC bit configures the synchronization when SYNCMODE is zero. 0 No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. 1 Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.
2 WPDIS	Write Protection Disable When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect. 0 Write protection is enabled. 1 Write protection is disabled.
1 INIT	Initialize The Channels Output When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect. The INIT bit is always read as 0.
0 FTMEN	FTM Enable This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Only the TPM-compatible registers (first set of registers) can be used without any restriction. Do not use the FTM-specific registers. 1 All registers including the FTM-specific registers (second set of registers) are available for use with no restrictions.

39.3.11 Synchronization (FTMx_SYNC)

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

NOTE

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See PWM synchronization.

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWSYNC	PWM Synchronization Software Trigger Selects the software trigger as the PWM synchronization trigger. The software trigger happens when a 1 is written to SWSYNC bit. 0 Software trigger is not selected. 1 Software trigger is selected.
6 TRIG2	PWM Synchronization Hardware Trigger 2

Table continues on the next page...

FTMx_SYNC field descriptions (continued)

Field	Description
	Enables hardware trigger 2 to the PWM synchronization. Hardware trigger 2 happens when a rising edge is detected at the trigger 2 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
5 TRIG1	PWM Synchronization Hardware Trigger 1 Enables hardware trigger 1 to the PWM synchronization. Hardware trigger 1 happens when a rising edge is detected at the trigger 1 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
4 TRIG0	PWM Synchronization Hardware Trigger 0 Enables hardware trigger 0 to the PWM synchronization. Hardware trigger 0 happens when a rising edge is detected at the trigger 0 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
3 SYNCHOM	Output Mask Synchronization Selects when the OUTMASK register is updated with the value of its buffer. 0 OUTMASK register is updated with the value of its buffer in all rising edges of the system clock. 1 OUTMASK register is updated with the value of its buffer only by the PWM synchronization.
2 REINIT	FTM Counter Reinitialization By Synchronization (FTM counter synchronization) Determines if the FTM counter is reinitialized when the selected trigger for the synchronization is detected. The REINIT bit configures the synchronization when SYNCMODE is zero. 0 FTM counter continues to count normally. 1 FTM counter is updated with its initial value when the selected trigger is detected.
1 CNTMAX	Maximum Loading Point Enable Selects the maximum loading point to PWM synchronization. See Boundary cycle and loading points. If CNTMAX is one, the selected loading point is when the FTM counter reaches its maximum value (MOD register). 0 The maximum loading point is disabled. 1 The maximum loading point is enabled.
0 CNTMIN	Minimum Loading Point Enable Selects the minimum loading point to PWM synchronization. See Boundary cycle and loading points. If CNTMIN is one, the selected loading point is when the FTM counter reaches its minimum value (CNTIN register). 0 The minimum loading point is disabled. 1 The minimum loading point is enabled.

1 CH1OI	Channel 1 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
0 CH0OI	Channel 0 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.

39.3.13 Output Mask (FTMx_OUTMASK)

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to PWM synchronization.

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FAULTEN3	Fault Control Enable For n = 6 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
29 SYNCEN3	Synchronization Enable For n = 6 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
28 DTEN3	Deadtime Enable For n = 6 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
27 DECAP3	Dual Edge Capture Mode Captures For n = 6 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when FTMEN = 1 and DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
26 DECAPEN3	Dual Edge Capture Mode Enable For n = 6 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 39-7. This field applies only when FTMEN = 1. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
25 COMP3	Complement Of Channel (n) for n = 6 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
24 COMBINE3	Combine Channels For n = 6 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 FAULTEN2	Fault Control Enable For n = 4 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
21 SYNCEN2	Synchronization Enable For n = 4 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
20 DTEN2	Deadtime Enable For n = 4 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
19 DECAP2	Dual Edge Capture Mode Captures For n = 4 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when FTMEN = 1 and DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
18 DECAPEN2	Dual Edge Capture Mode Enable For n = 4 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 39-7. This field applies only when FTMEN = 1. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
17 COMP2	Complement Of Channel (n) For n = 4 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
16 COMBINE2	Combine Channels For n = 4 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 FAULTEN1	Fault Control Enable For n = 2 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
13 SYNCEN1	Synchronization Enable For n = 2 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
12 DTEN1	Deadtime Enable For n = 2 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
11 DECAP1	Dual Edge Capture Mode Captures For n = 2 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when FTMEN = 1 and DECAPEN = 1. DECAP bit is cleared automatically by hardware if Dual Edge Capture – One-Shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
10 DECAPEN1	Dual Edge Capture Mode Enable For n = 2 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 39-7. This field applies only when FTMEN = 1. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
9 COMP1	Complement Of Channel (n) For n = 2 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
8 COMBINE1	Combine Channels For n = 2 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FAULTEN0	Fault Control Enable For n = 0 Enables the fault control in channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The fault control in this pair of channels is disabled. 1 The fault control in this pair of channels is enabled.
5 SYNCEN0	Synchronization Enable For n = 0 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
4 DTEN0	Deadtime Enable For n = 0 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
3 DECAP0	Dual Edge Capture Mode Captures For n = 0 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits. This field applies only when FTMEN = 1 and DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
2 DECAPEN0	Dual Edge Capture Mode Enable For n = 0 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 39-7. This field applies only when FTMEN = 1. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
1 COMP0	Complement Of Channel (n) For n = 0 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
0 COMBINE0	Combine Channels For n = 0 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.

39.3.15 Deadtime Insertion Control (FTMx_DEADTIME)

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 68h offset

Bit	31–8	7	6	5	4	3	2	1	0
R	0	DTPS		DTVAL					
W									
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0	0	0	0	0	0	0	0

FTMx_DEADTIME field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 DTPS	Deadtime Prescaler Value Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0x Divide the system clock by 1. 10 Divide the system clock by 4. 11 Divide the system clock by 16.
5–0 DTVAL	Deadtime Value Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS. Deadtime insert value = (DTPS × DTVAL). DTVAL selects the number of deadtime counts inserted as follows: When DTVAL is 0, no counts are inserted. When DTVAL is 1, 1 count is inserted. When DTVAL is 2, 2 counts are inserted. This pattern continues up to a possible 63 counts. This field is write protected. It can be written only when MODE[WPDIS] = 1.

39.3.16 FTM External Trigger (FTMx_EXTTRIG)

This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period.

Channels 6 and 7 are not used to generate channel triggers.

Address: Base address + 6Ch offset

FTMx_EXTTRIG field descriptions

Field	Description
31–8 Reserved	This field is reserved.
7 TRIGF	Channel Trigger Flag Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect. If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF. 0 No channel trigger was generated. 1 A channel trigger was generated.
6 INITTRIGEN	Initialization Trigger Enable Enables the generation of the trigger when the FTM counter is equal to the CNTIN register. 0 The generation of initialization trigger is disabled. 1 The generation of initialization trigger is enabled.
5 CH1TRIG	Channel 1 Trigger Enable Enable the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
4 CH0TRIG	Channel 0 Trigger Enable Enable the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
3 CH5TRIG	Channel 5 Trigger Enable Enable the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
2 CH4TRIG	Channel 4 Trigger Enable Enable the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
1 CH3TRIG	Channel 3 Trigger Enable Enable the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
0 CH2TRIG	Channel 2 Trigger Enable Enable the generation of the channel trigger when the FTM counter is equal to the CnV register.

Table continues on the next page...

FTMx_EXTTRIG field descriptions (continued)

Field	Description
	0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.

39.3.17 Channels Polarity (FTMx_POL)

This register defines the output polarity of the FTM channels.

NOTE

The safe value that is driven in a channel output when the fault control is enabled and a fault condition is detected is the inactive state of the channel. That is, the safe value of a channel is the value of its POL bit.

Address: Base address + 70h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FTMx_POL field descriptions

Field	Description
31–8 Reserved	This field is reserved.
7 POL7	Channel 7 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
6 POL6	Channel 6 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
5 POL5	Channel 5 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1.

Table continues on the next page...

FTMx_POL field descriptions (continued)

Field	Description
	0 The channel polarity is active high. 1 The channel polarity is active low.
4 POL4	Channel 4 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
3 POL3	Channel 3 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
2 POL2	Channel 2 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
1 POL1	Channel 1 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
0 POL0	Channel 0 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.

39.3.18 Fault Mode Status (FTMx_FMS)

This register contains the fault detection flags, write protection enable bit, and the logic OR of the enabled fault inputs.

Address: Base address + 74h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

FTMx_FMS field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 FAULTF	Fault Detection Flag Represents the logic OR of the individual FAULTFj bits where j = 3, 2, 1, 0. Clear FAULTF by reading the FMS register while FAULTF is set and then writing a 0 to FAULTF while there is no existing fault condition at the enabled fault inputs. Writing a 1 to FAULTF has no effect. If another fault condition is detected in an enabled fault input before the clearing sequence is completed, the sequence is reset so FAULTF remains set after the clearing sequence is completed for the earlier fault condition. FAULTF is also cleared when FAULTFj bits are cleared individually. 0 No fault condition was detected. 1 A fault condition was detected.

Table continues on the next page...

FTMx_FMS field descriptions (continued)

Field	Description
6 WPEN	Write Protection Enable The WPEN bit is the negation of the WPDIS bit. WPEN is set when 1 is written to it. WPEN is cleared when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPEN has no effect. 0 Write protection is disabled. Write protected bits can be written. 1 Write protection is enabled. Write protected bits cannot be written.
5 FAULTIN	Fault Inputs Represents the logic OR of the enabled fault inputs after their filter (if their filter is enabled) when fault control is enabled. 0 The logic OR of the enabled fault inputs is 0. 1 The logic OR of the enabled fault inputs is 1.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FAULTF3	Fault Detection Flag 3 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF3 by reading the FMS register while FAULTF3 is set and then writing a 0 to FAULTF3 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF3 has no effect. FAULTF3 bit is also cleared when FAULTF bit is cleared. If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF3 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.
2 FAULTF2	Fault Detection Flag 2 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF2 by reading the FMS register while FAULTF2 is set and then writing a 0 to FAULTF2 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF2 has no effect. FAULTF2 bit is also cleared when FAULTF bit is cleared. If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF2 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.
1 FAULTF1	Fault Detection Flag 1 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF1 by reading the FMS register while FAULTF1 is set and then writing a 0 to FAULTF1 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF1 has no effect. FAULTF1 bit is also cleared when FAULTF bit is cleared.

Table continues on the next page...

FTMx_FMS field descriptions (continued)

Field	Description
	If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF1 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.
0 FAULTF0	Fault Detection Flag 0 Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input. Clear FAULTF0 by reading the FMS register while FAULTF0 is set and then writing a 0 to FAULTF0 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF0 has no effect. FAULTF0 bit is also cleared when FAULTF bit is cleared. If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF0 remains set after the clearing sequence is completed for the earlier fault condition. 0 No fault condition was detected at the fault input. 1 A fault condition was detected at the fault input.

39.3.19 Input Capture Filter Control (FTMx_FILTER)

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

NOTE

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

Address: Base address + 78h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FTMx_QDCTRL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PHAFLTREN	Phase A Input Filter Enable Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero. 0 Phase A input filter is disabled. 1 Phase A input filter is enabled.
6 PHBFLTREN	Phase B Input Filter Enable Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero. 0 Phase B input filter is disabled. 1 Phase B input filter is enabled.
5 PHAPOL	Phase A Input Polarity Selects the polarity for the quadrature decoder phase A input. 0 Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.
4 PHBPOL	Phase B Input Polarity Selects the polarity for the quadrature decoder phase B input. 0 Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.
3 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in the Quadrature Decoder mode. 0 Phase A and phase B encoding mode. 1 Count and direction encoding mode.
2 QUADIR	FTM Counter Direction In Quadrature Decoder Mode Indicates the counting direction. 0 Counting direction is decreasing (FTM counter decrement). 1 Counting direction is increasing (FTM counter increment).
1 TOFDIR	Timer Overflow Direction In Quadrature Decoder Mode Indicates if the TOF bit was set on the top or the bottom of counting. 0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register). 1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).

FTMx_QDCTRL field descriptions (continued)

Field	Description
0 QUADEN	Quadrature Decoder Mode Enable Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See Table 39-7. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Quadrature Decoder mode is disabled. 1 Quadrature Decoder mode is enabled.

39.3.22 Configuration (FTMx_CONF)

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset

39.3.25 FTM Inverting Control (FTMx_INVCTRL)

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

Address: Base address + 90h offset

39.3.26 FTM Software Output Control (FTMx_SWOCTRL)

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

39.4 Functional description

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

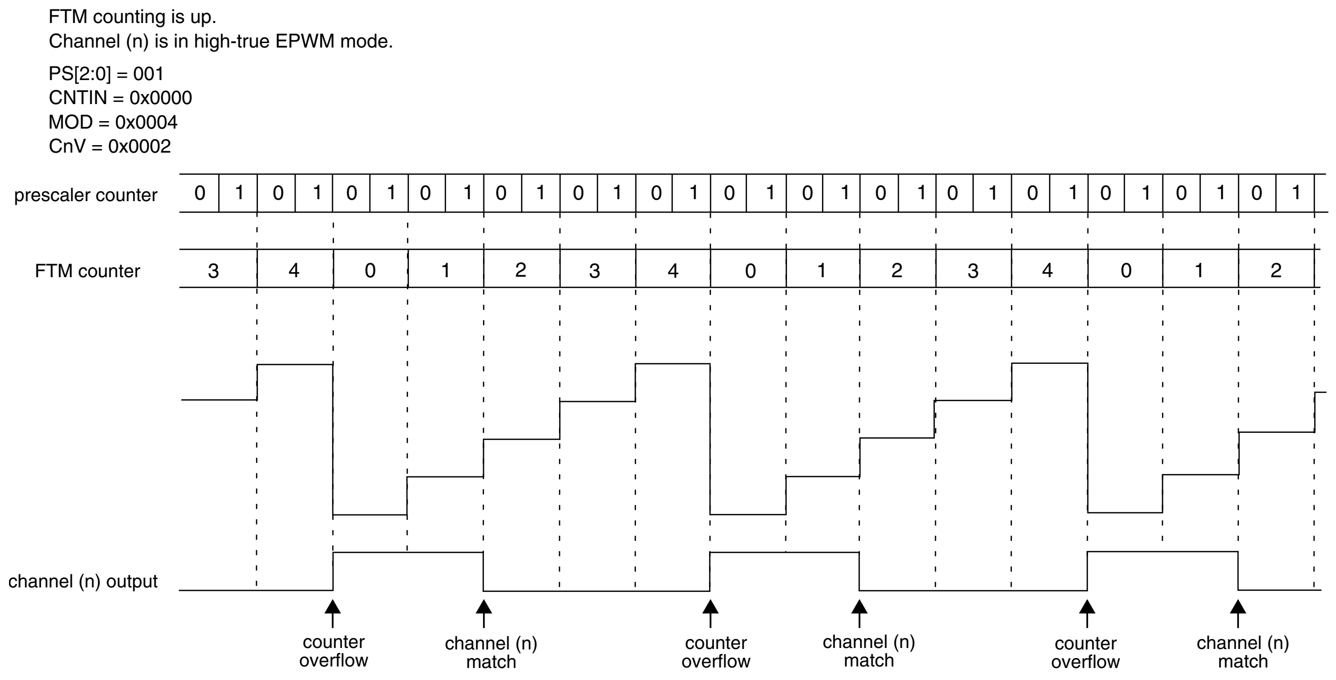

Figure 39-207. Notation used

39.4.1 Clock source

The FTM has only one clock domain: the system clock.

39.4.1.1 Counter clock source

The CLKS[1:0] bits in the SC register select one of three possible clock sources for the FTM counter or disable the FTM counter. After any MCU reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration. Refer to the chip specific documentation for further information. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to assure that counter transitions are properly aligned to system clock transitions.Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

39.4.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

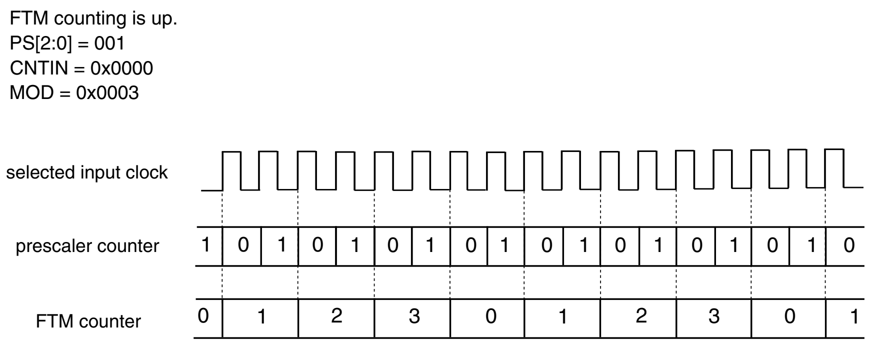

Figure 39-208. Example of the prescaler counter

39.4.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- Up counting
- Up-down counting
- Quadrature Decoder mode

39.4.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is (MOD – CNTIN + 0x0001) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

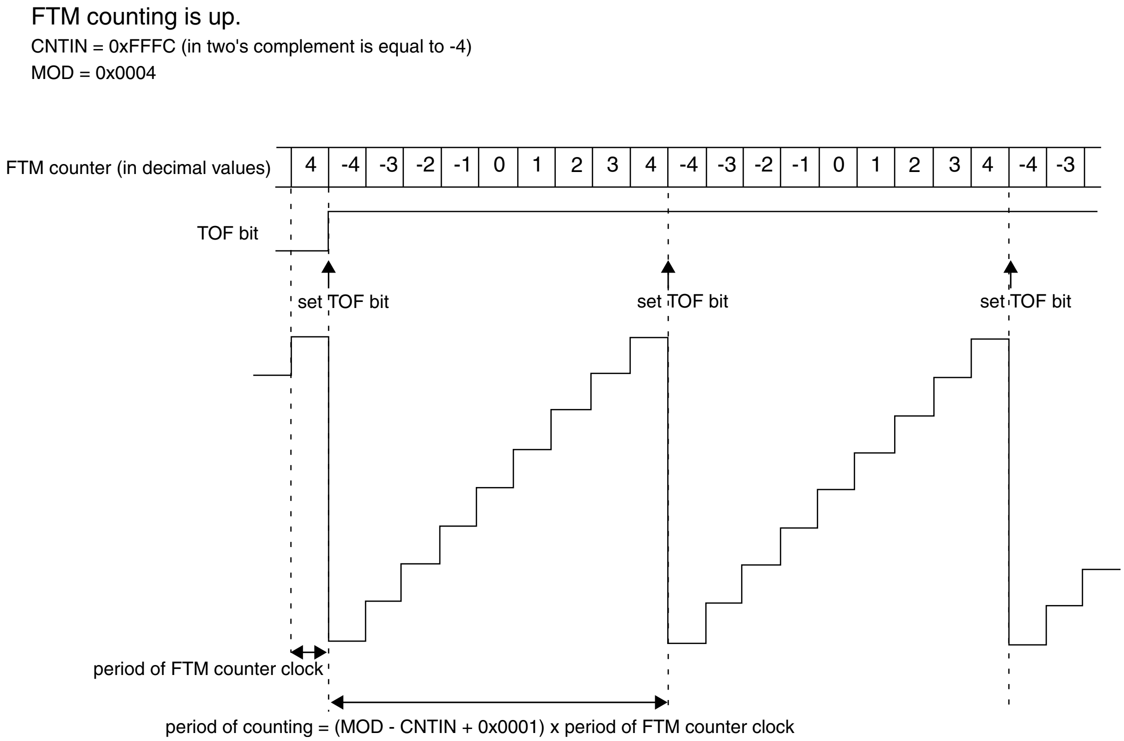

Figure 39-209. Example of FTM up and signed counting

Table 39-302. FTM counting based on CNTIN value

When	Then
CNTIN = 0x0000	The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.
CNTIN[15] = 1	The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed.
CNTIN[15] = 0 and CNTIN ≠ 0x0000	The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.

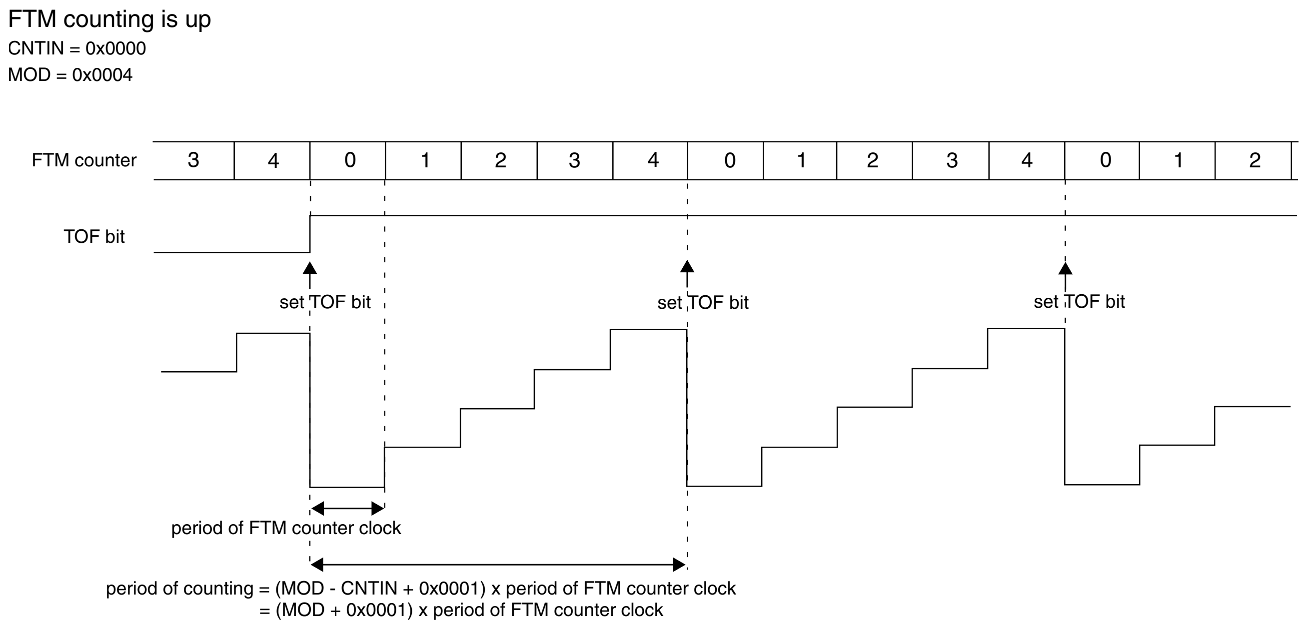

Figure 39-210. Example of FTM up counting with CNTIN = 0x0000

Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

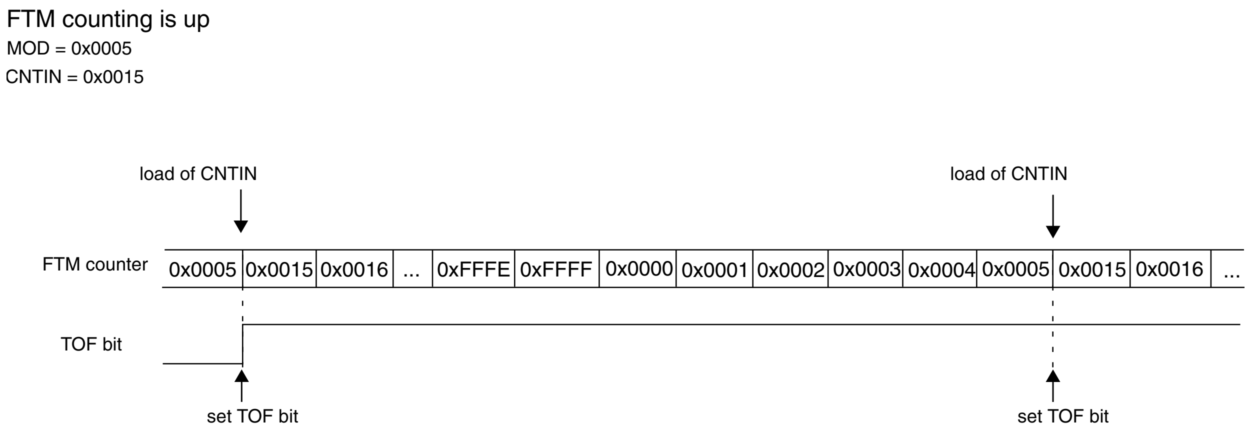

Figure 39-211. Example of up counting when the value of CNTIN is greater than the value of MOD

39.4.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is 2 × (MOD – CNTIN) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

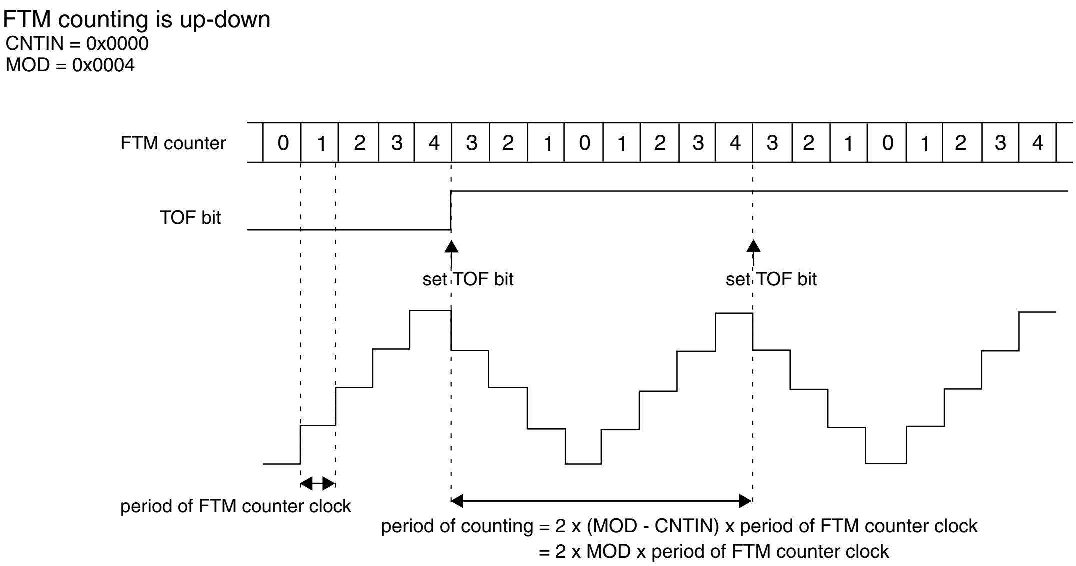

Figure 39-212. Example of up-down counting when CNTIN = 0x0000

Note

It is expected that the up-down counting be used only with CNTIN = 0x0000.

39.4.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

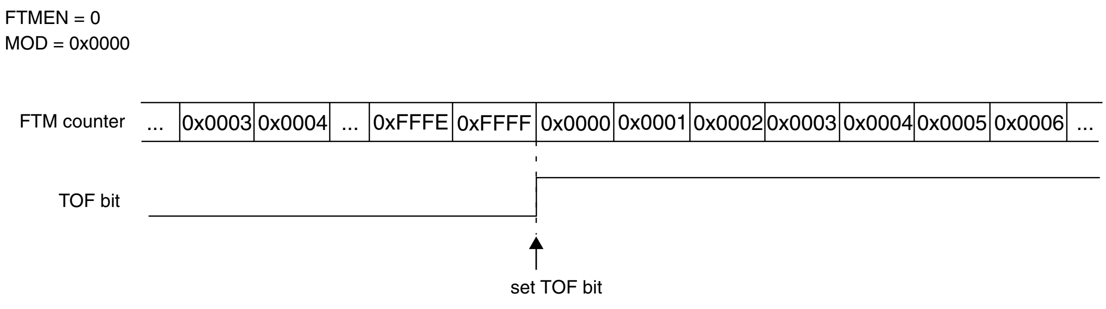

Figure 39-213. Example when the FTM counter is free running

The FTM counter is also a free running counter when:

- FTMEN = 1
- QUADEN = 0
- CPWMS = 0

- CNTIN = 0x0000, and
- MOD = 0xFFFF

39.4.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- FTM counter synchronization.

39.4.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

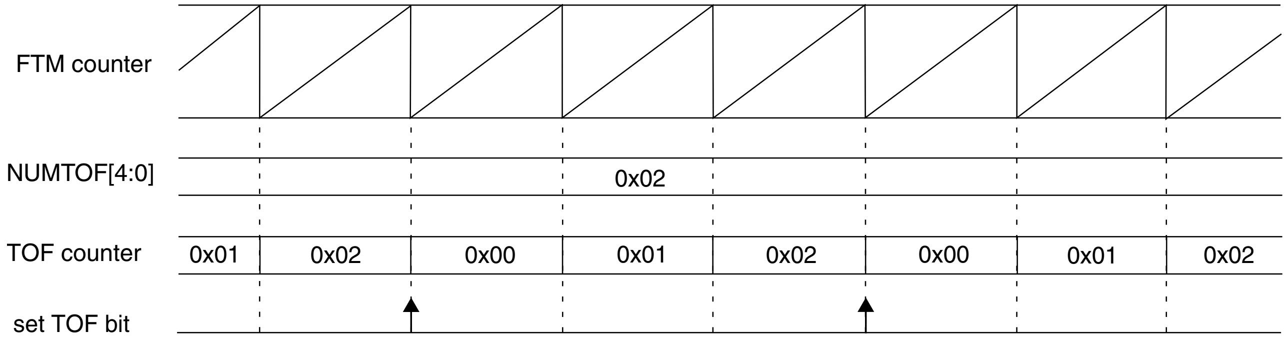

Figure 39-214. Periodic TOF when NUMTOF = 0x02

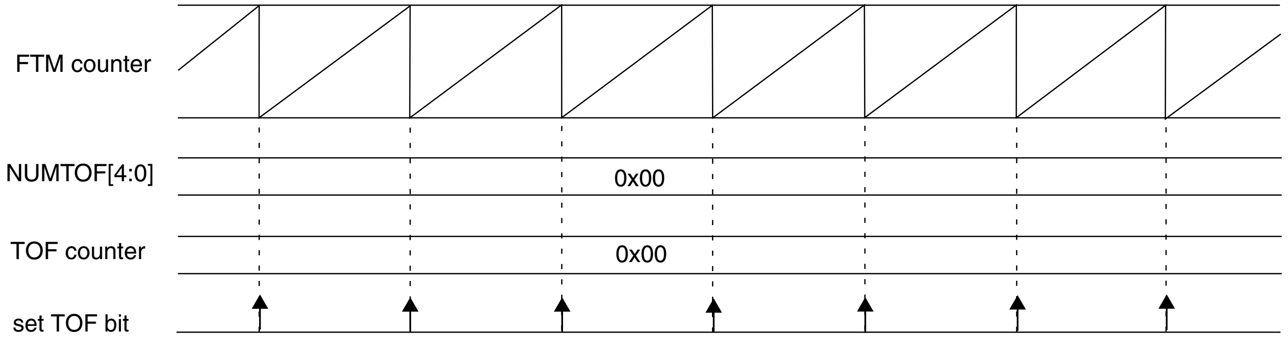

Figure 39-215. Periodic TOF when NUMTOF = 0x00

39.4.4 Input Capture mode

The Input Capture mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0
- MSnB:MSnA = 0:0, and
- ELSnB:ELSnA ≠ 0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

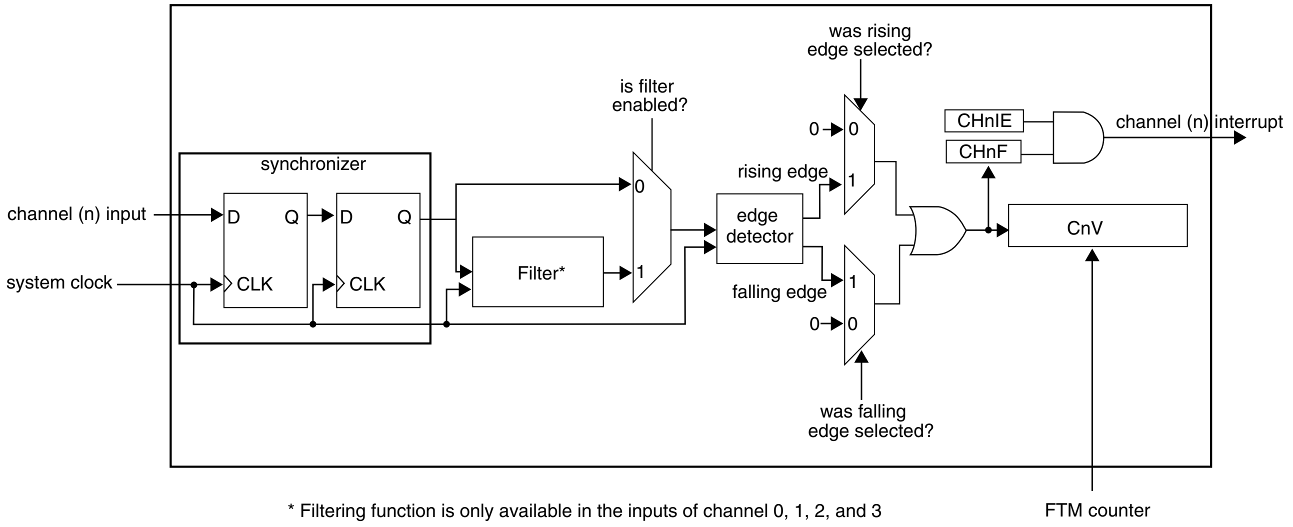

Figure 39-216. Input Capture mode

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

Note

The Input Capture mode must be used only with CNTIN = 0x0000.

39.4.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

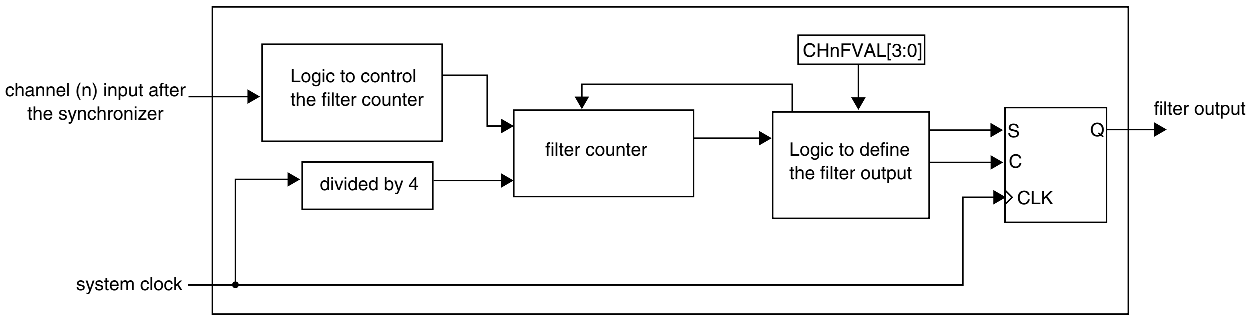

Figure 39-217. Channel input filter

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by CHnFVAL[3:0] (× 4 system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If (CHnFVAL[3:0] ≠ 0000), then the input signal is delayed by the minimum pulse width (CHnFVAL[3:0] × 4 system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer,

one rising edge to the filter output, plus one more to the edge detector. In other words, CHnF is set (4 + 4 × CHnFVAL[3:0]) system clock periods after a valid edge occurs on the channel input.

The clock for the counter in the channel input filter is the system clock divided by 4.

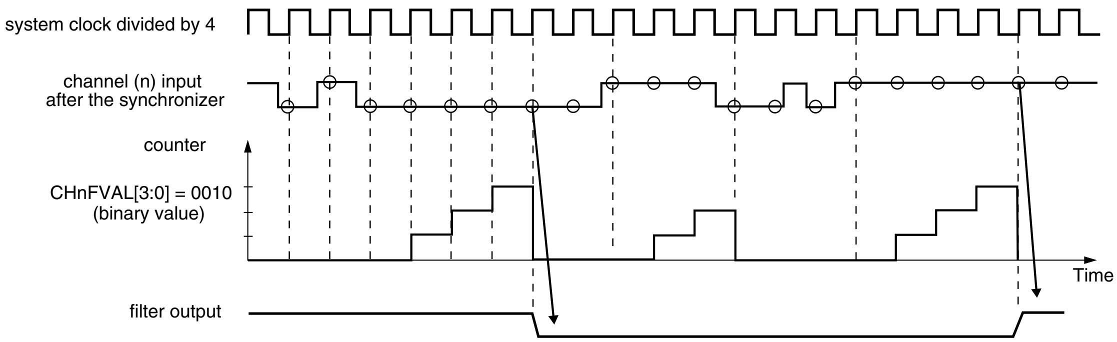

Figure 39-218. Channel input filter example

39.4.5 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB:MSnA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

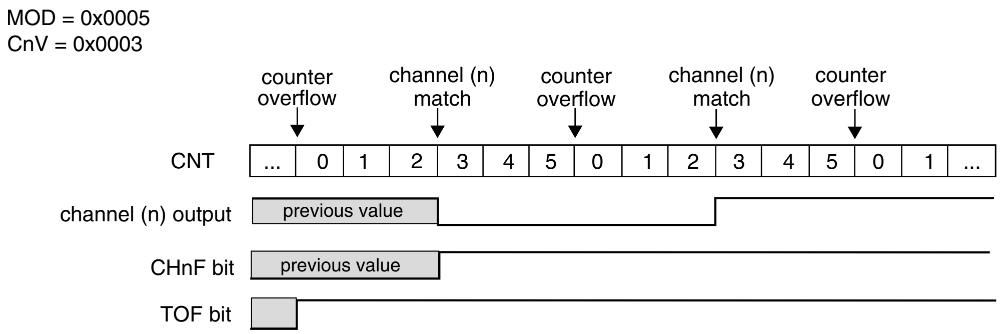

Figure 39-219. Example of the Output Compare mode when the match toggles the channel output

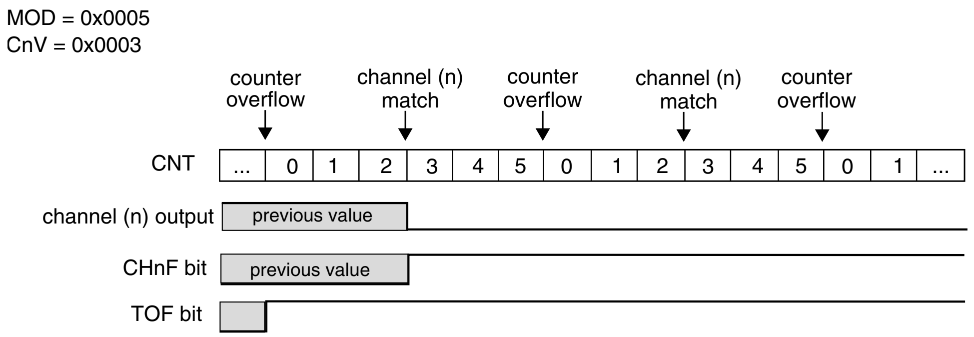

Figure 39-220. Example of the Output Compare mode when the match clears the channel output

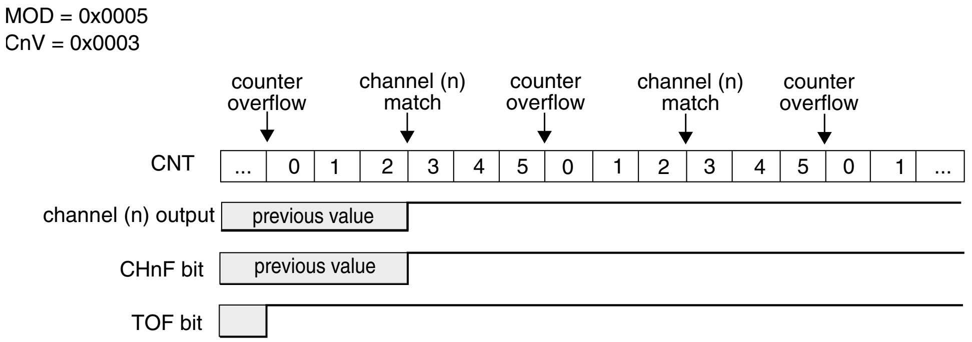

Figure 39-221. Example of the Output Compare mode when the match sets the channel output

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

Note

The Output Compare mode must be used only with CNTIN = 0x0000.

39.4.6 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB = 1

The EPWM period is determined by (MOD − CNTIN + 0x0001) and the pulse width (duty cycle) is determined by (CnV − CNTIN).

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

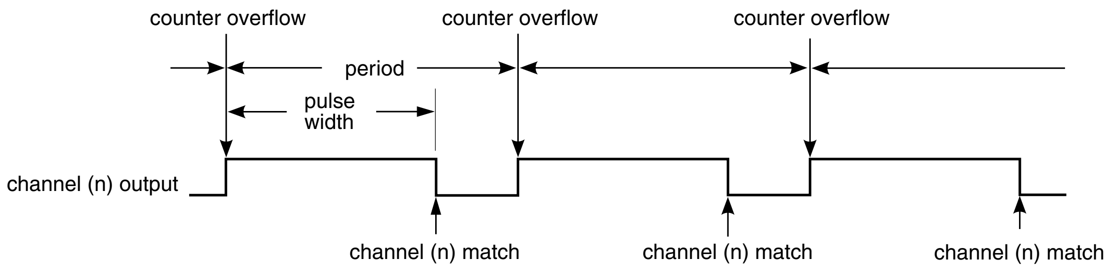

Figure 39-222. EPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

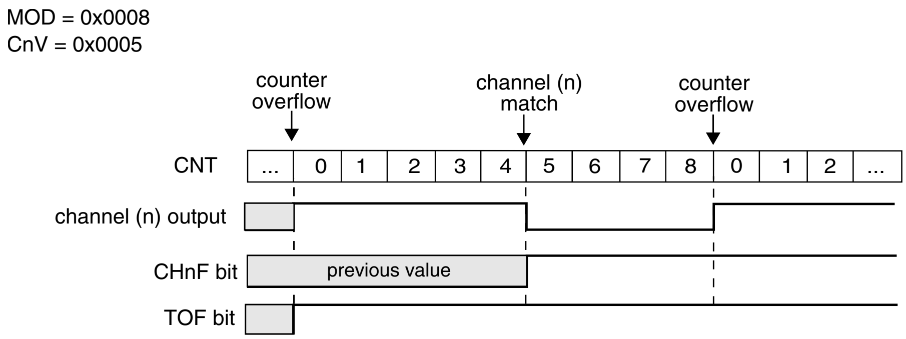

Figure 39-223. EPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

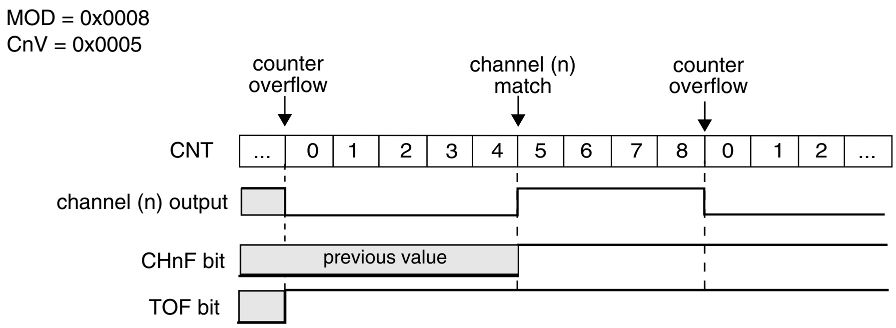

Figure 39-224. EPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match. If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

Note

The EPWM mode must be used only with CNTIN = 0x0000.

39.4.7 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by 2 × (CnV − CNTIN) and the period is determined by 2 × (MOD − CNTIN). See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

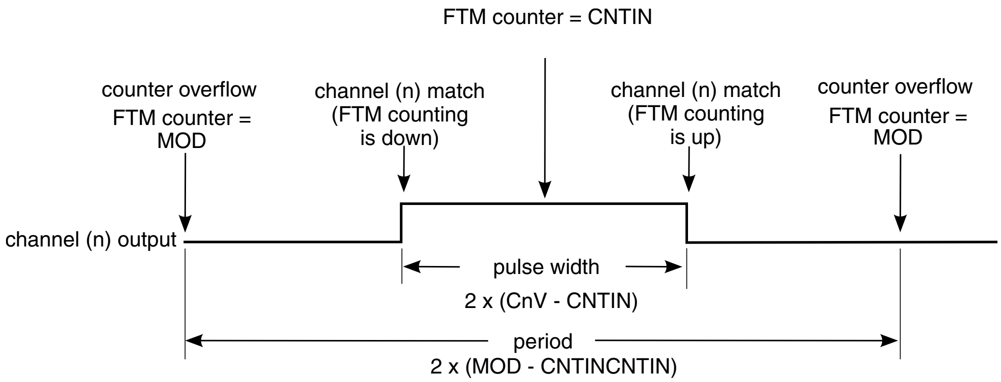

Figure 39-225. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

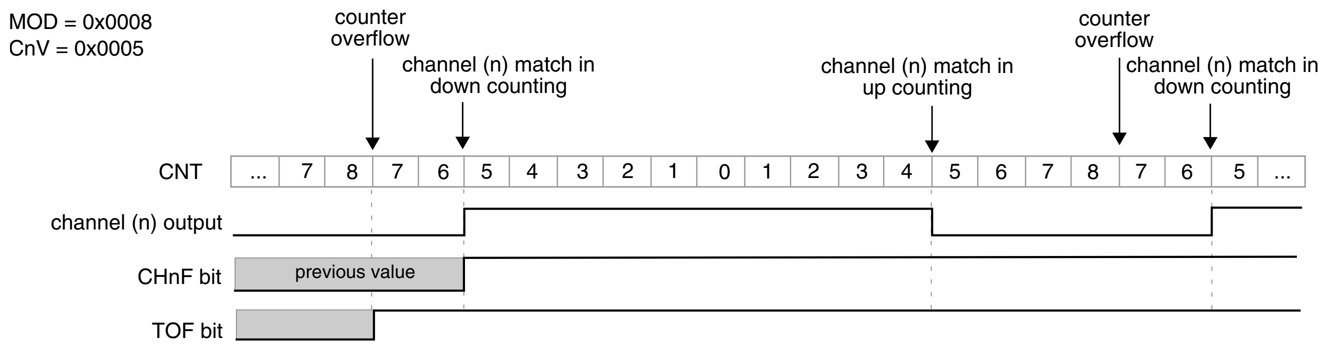

Figure 39-226. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

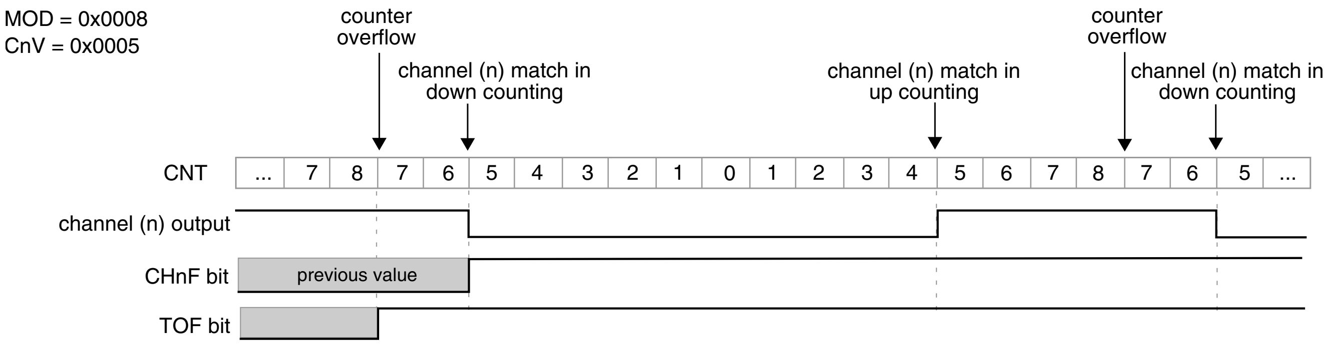

Figure 39-227. CPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

Note

The CPWM mode must be used only with CNTIN = 0x0000.

39.4.8 Combine mode

The Combine mode is selected when:

- FTMEN = 1
- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1, and
- CPWMS = 0

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD − CNTIN + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)V − C(n)V|).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)V). The CH(n+1)F bit is set and the channel (n +1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n +1)V). It is forced high at the channel (n) match (FTM counter = C(n)V). See the following figure.

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n +1)V). It is forced low at the channel (n) match (FTM counter = C(n)V). See the following figure.

In Combine mode, the ELS(n+1)B and ELS(n+1)A bits are not used in the generation of the channels (n) and (n+1) output. However, if (ELSnB:ELSnA = 0:0) then the channel (n) output is not controlled by FTM, and if (ELS(n+1)B:ELS(n+1)A = 0:0) then the channel (n+1) output is not controlled by FTM.

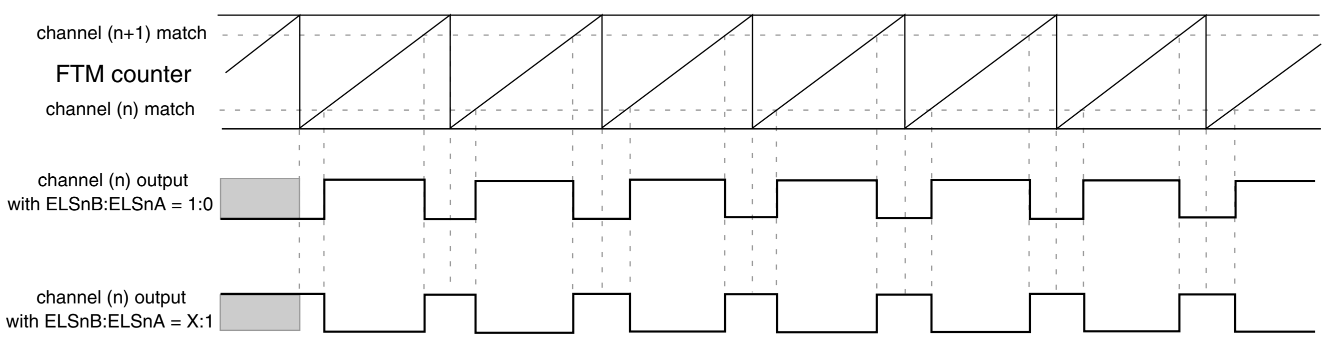

Figure 39-228. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

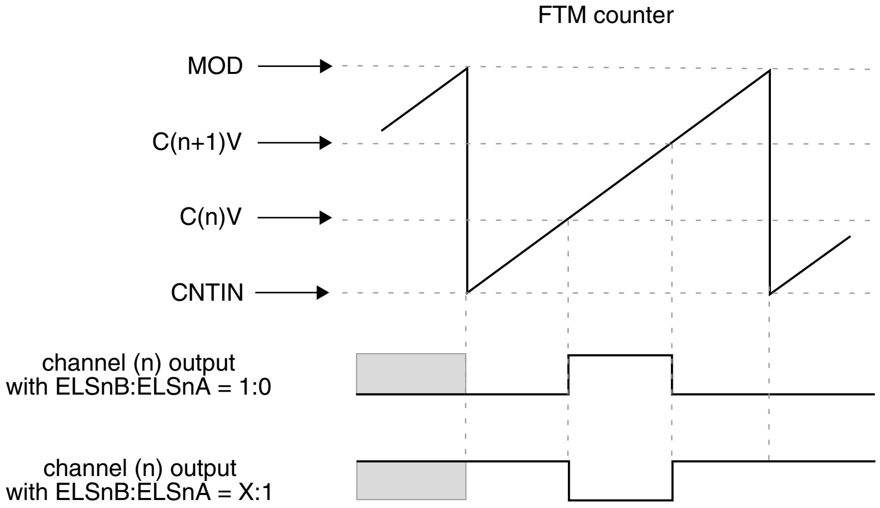

Figure 39-229. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V < C(n+1)V)

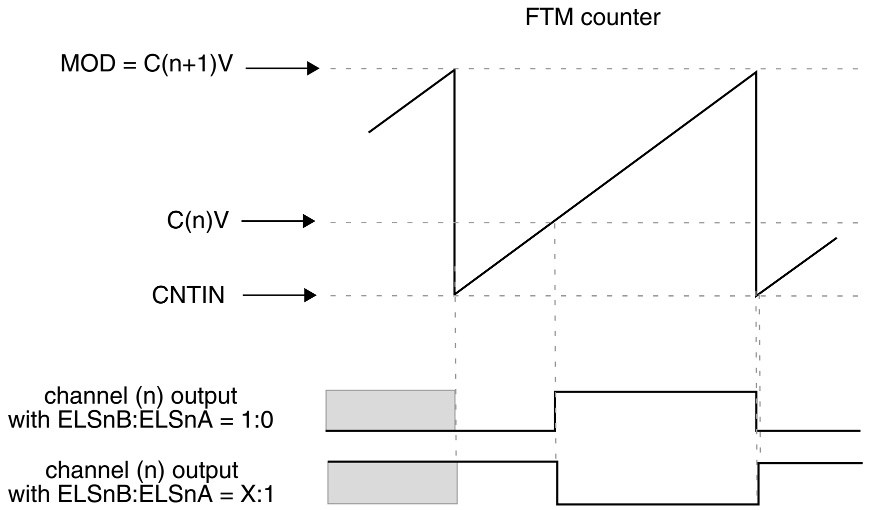

Figure 39-230. Channel (n) output if (CNTIN < C(n)V < MOD) and (C(n+1)V = MOD)

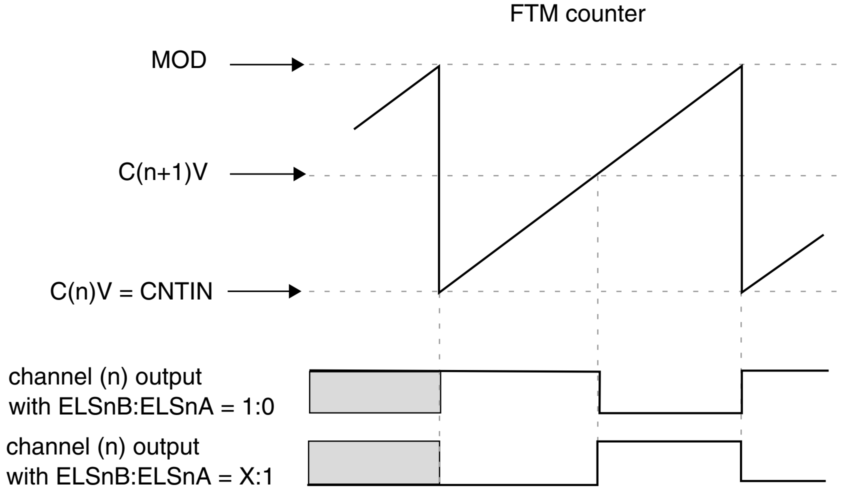

Figure 39-231. Channel (n) output if (C(n)V = CNTIN) and (CNTIN < C(n+1)V < MOD)

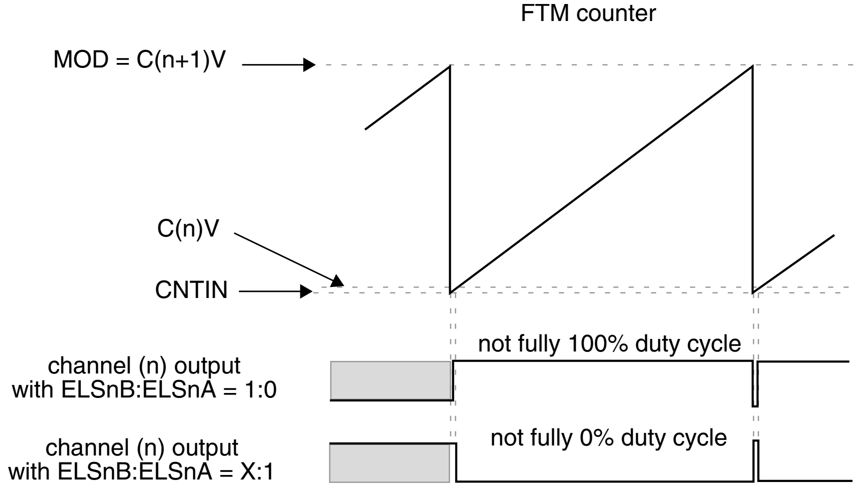

Figure 39-232. Channel (n) output if (CNTIN < C(n)V < MOD) and (C(n)V is Almost Equal to CNTIN) and (C(n+1)V = MOD)

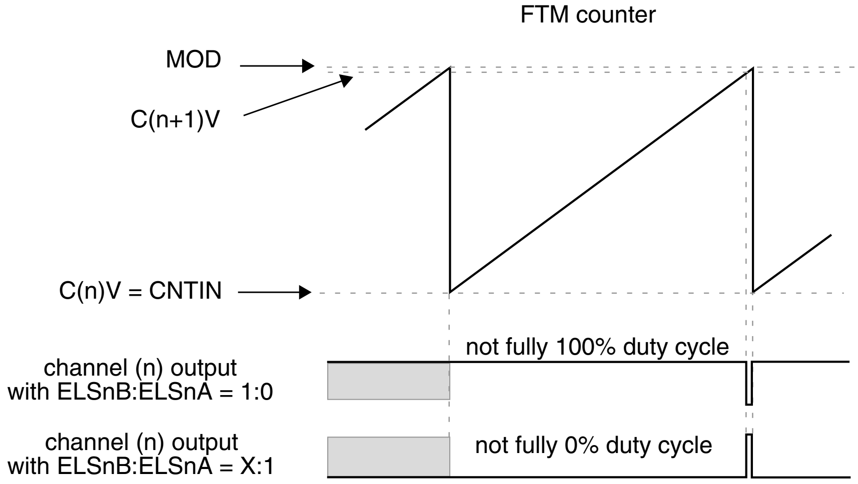

Figure 39-233. Channel (n) output if (C(n)V = CNTIN) and (CNTIN < C(n+1)V < MOD) and (C(n+1)V is Almost Equal to MOD)

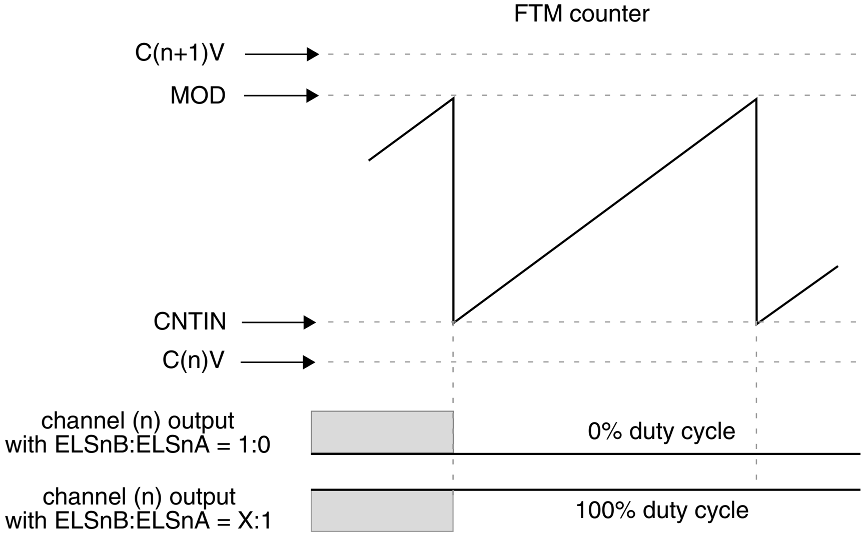

Figure 39-234. Channel (n) output if C(n)V and C(n+1)V are not between CNTIN and MOD

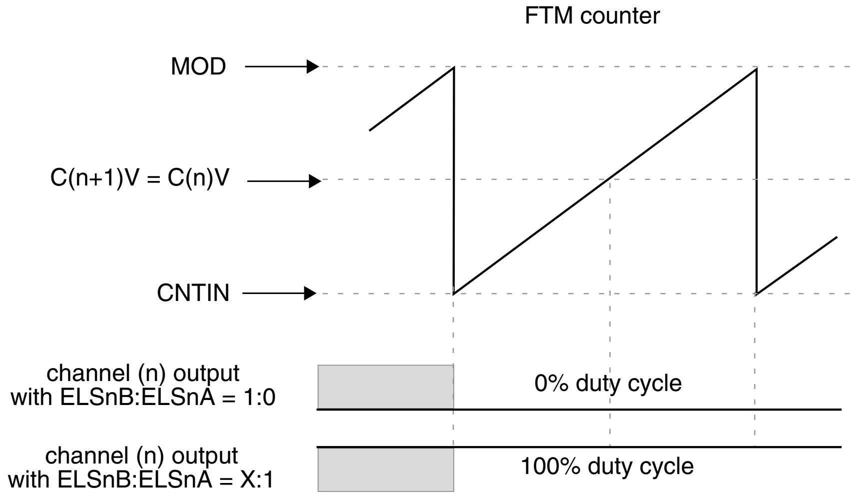

Figure 39-235. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V = C(n+1)V)

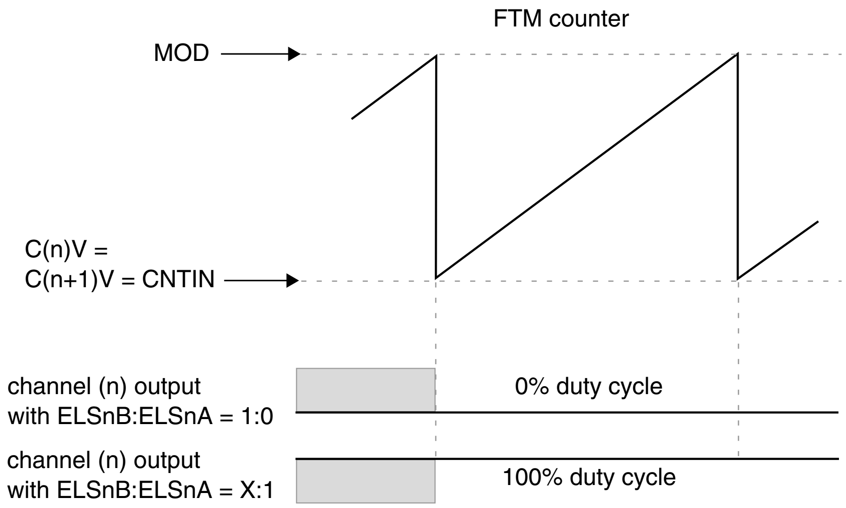

Figure 39-236. Channel (n) output if (C(n)V = C(n+1)V = CNTIN)

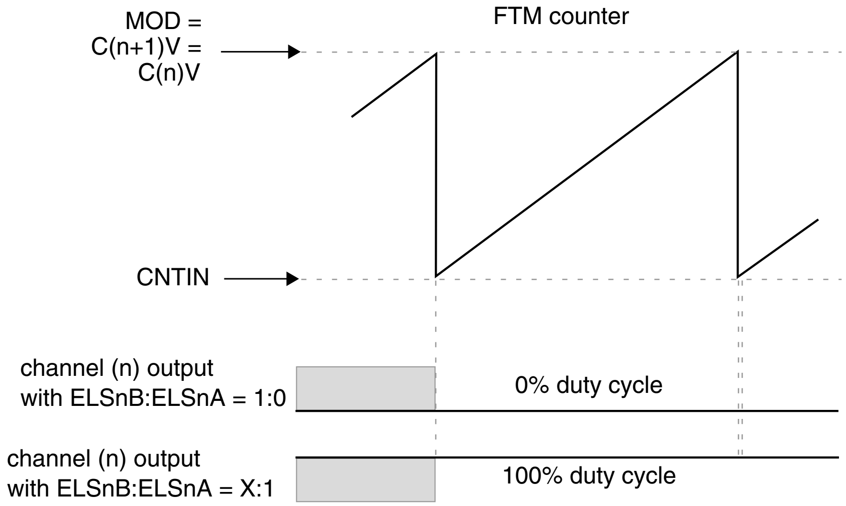

Figure 39-237. Channel (n) output if (C(n)V = C(n+1)V = MOD)

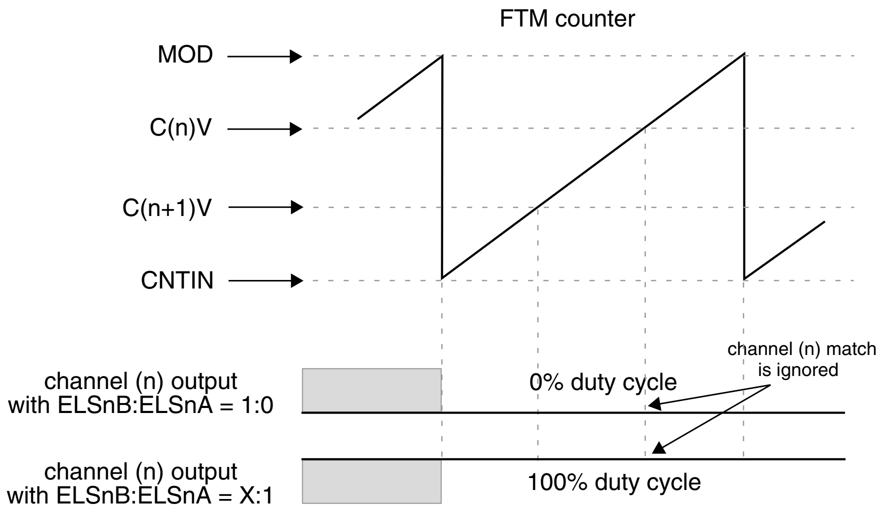

Figure 39-238. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V > C(n+1)V)

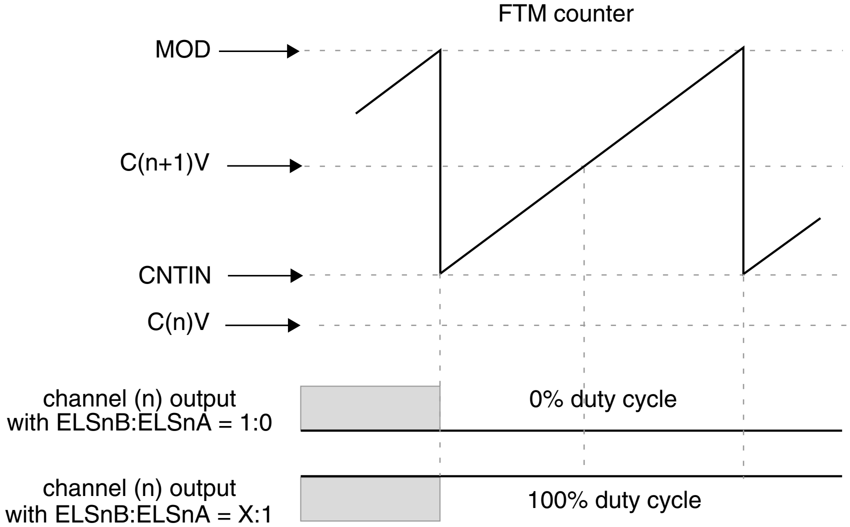

Figure 39-239. Channel (n) output if (C(n)V < CNTIN) and (CNTIN < C(n+1)V < MOD)

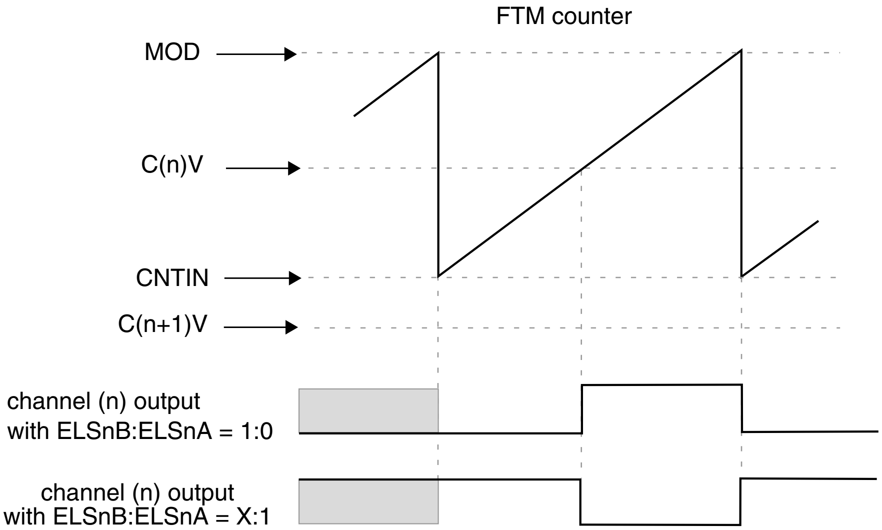

Figure 39-240. Channel (n) output if (C(n+1)V < CNTIN) and (CNTIN < C(n)V < MOD)

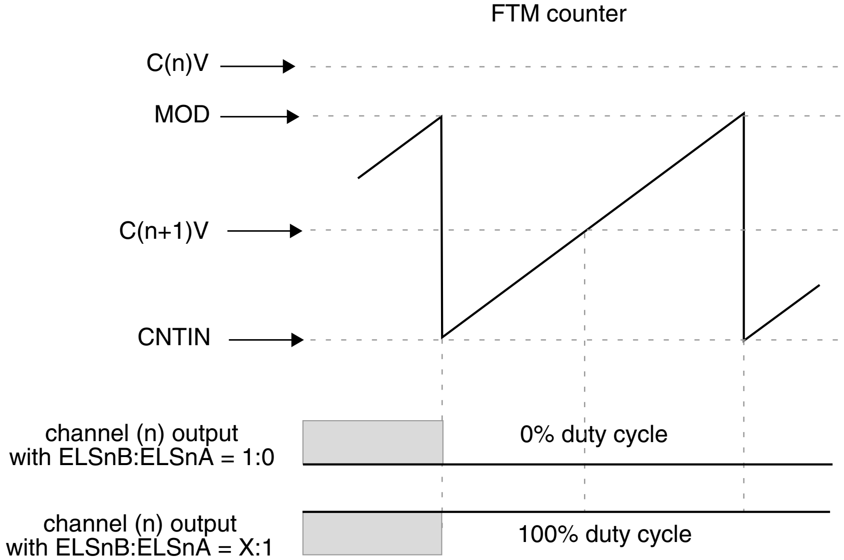

Figure 39-241. Channel (n) output if (C(n)V > MOD) and (CNTIN < C(n+1)V < MOD)

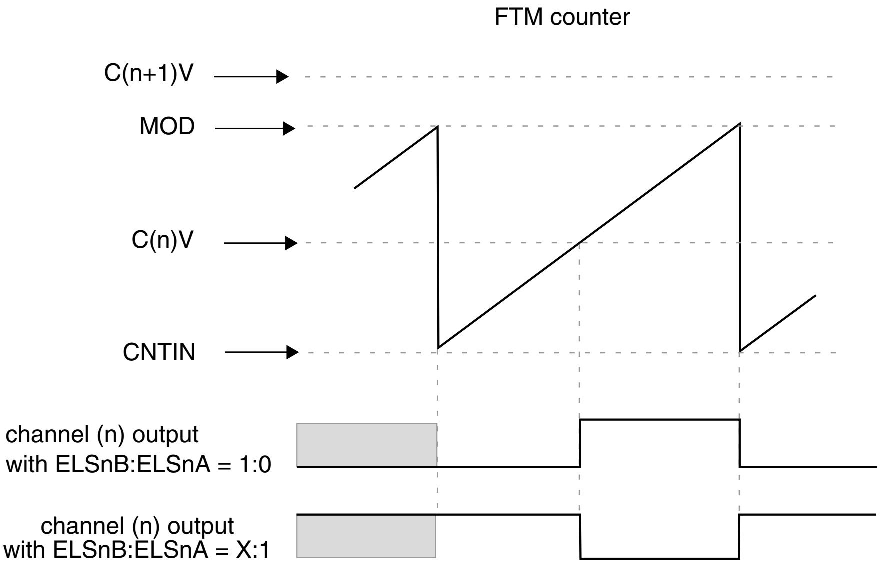

Figure 39-242. Channel (n) output if (C(n+1)V > MOD) and (CNTIN < C(n)V < MOD)

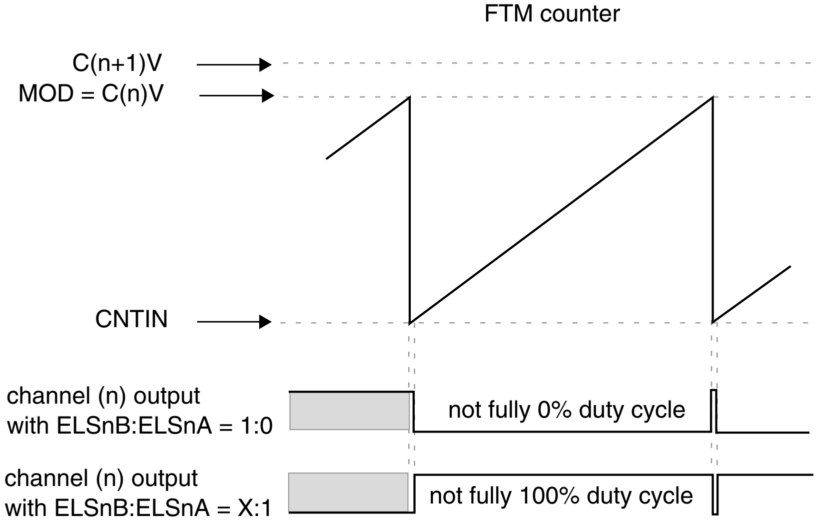

Figure 39-243. Channel (n) output if (C(n+1)V > MOD) and (CNTIN < C(n)V = MOD)

39.4.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter = C(n)V, is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter = C(n+1)V. So, Combine mode allows the generation of asymmetrical PWM signals.

39.4.9 Complementary mode

The Complementary mode is selected when:

- FTMEN = 1
- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1
- CPWMS = 0, and
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- FTMEN = 1
- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1

- CPWMS = 0, and
- COMP = 0

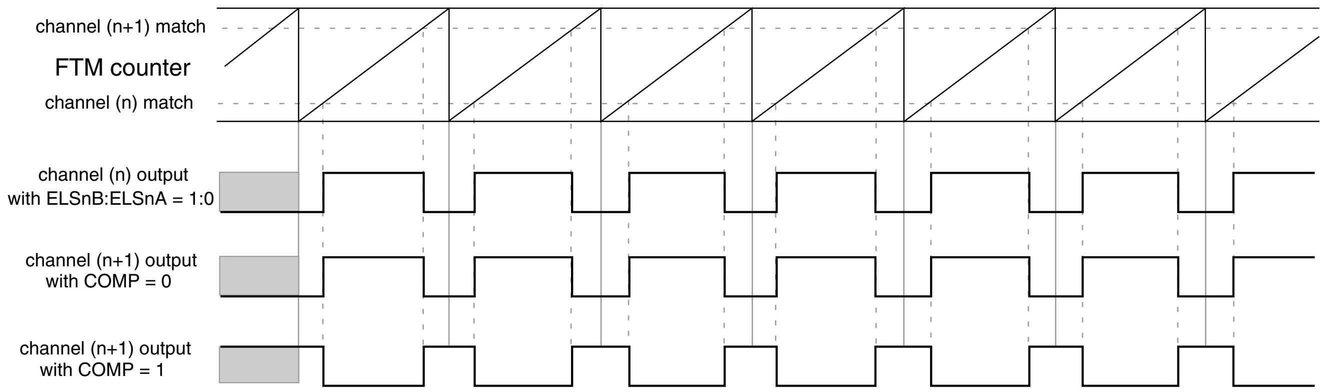

Figure 39-244. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = 1:0)

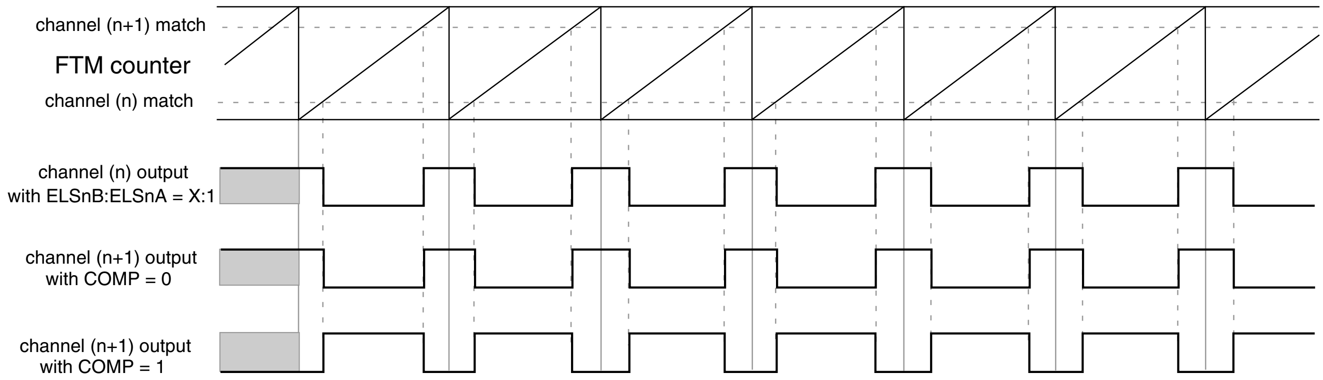

Figure 39-245. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = X:1)

39.4.10 Registers updated from write buffers

39.4.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

Table 39-303. CNTIN register update

When	Then CNTIN register is updated
CLKS[1:0] = 0:0	When CNTIN register is written, independent of FTMEN bit.
• FTMEN = 0, or • CNTINC = 0	At the next system clock after CNTIN was written.
• FTMEN = 1, • SYNCMODE = 1, and • CNTINC = 1	By the CNTIN register synchronization.

39.4.10.2 MOD register update

The following table describes when MOD register is updated:

Table 39-304. MOD register update

When	Then MOD register is updated
CLKS[1:0] = 0:0	When MOD register is written, independent of FTMEN bit.
• CLKS[1:0] ≠ 0:0, and • FTMEN = 0	According to the CPWMS bit, that is: • If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. • If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).
• CLKS[1:0] ≠ 0:0, and • FTMEN = 1	By the MOD register synchronization.

39.4.10.3 CnV register update

The following table describes when CnV register is updated:

Table 39-305. CnV register update

When	Then CnV register is updated
CLKS[1:0] = 0:0	When CnV register is written, independent of FTMEN bit.
• CLKS[1:0] ≠ 0:0, and • FTMEN = 0	According to the selected mode, that is: • If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written. • If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. • If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).
• CLKS[1:0] ≠ 0:0, and • FTMEN = 1	According to the selected mode, that is: • If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization. • If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization.

39.4.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

Note

- The PWM synchronization must be used only in Combine mode.
- The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

39.4.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when TRIGn = 1, where n = 0, 1 or 2 corresponding to each one of the input signals, respectively. The hardware trigger input n is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the TRIGn bit is cleared when 0 is written to it or when the trigger n event is detected.

In this case, if two or more hardware triggers are enabled (for example, TRIG0 and TRIG1 = 1) and only trigger 1 event occurs, then only TRIG1 bit is cleared. If a trigger n event occurs together with a write setting TRIGn bit, then the synchronization is initiated, but TRIGn bit remains set due to the write operation.

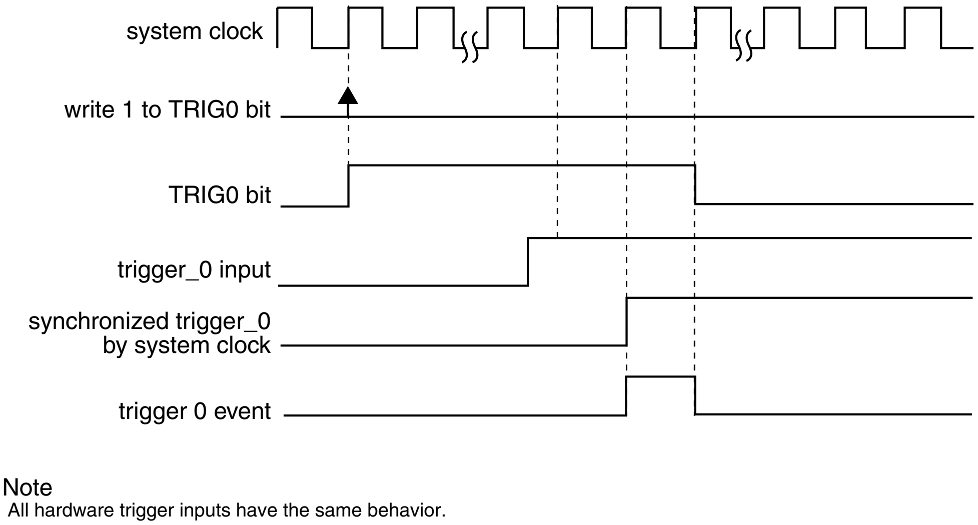

Figure 39-246. Hardware trigger event with HWTRIGMODE = 0

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

39.4.11.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see Boundary cycle and loading points and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

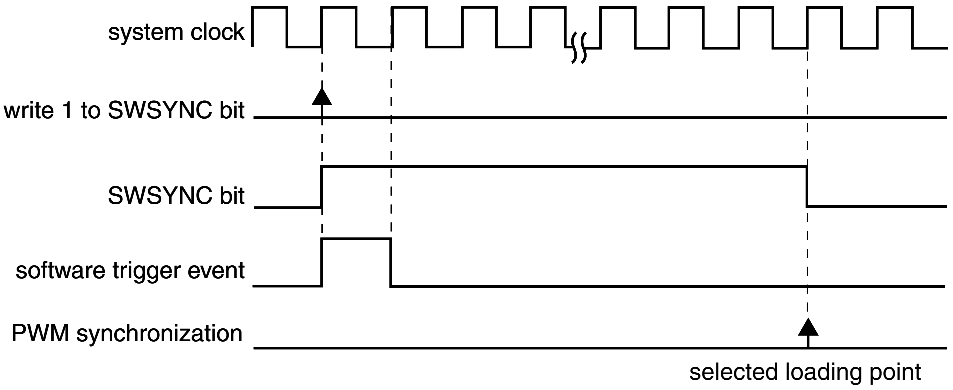

Figure 39-247. Software trigger event

39.4.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In Up counting mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in Up-down counting mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

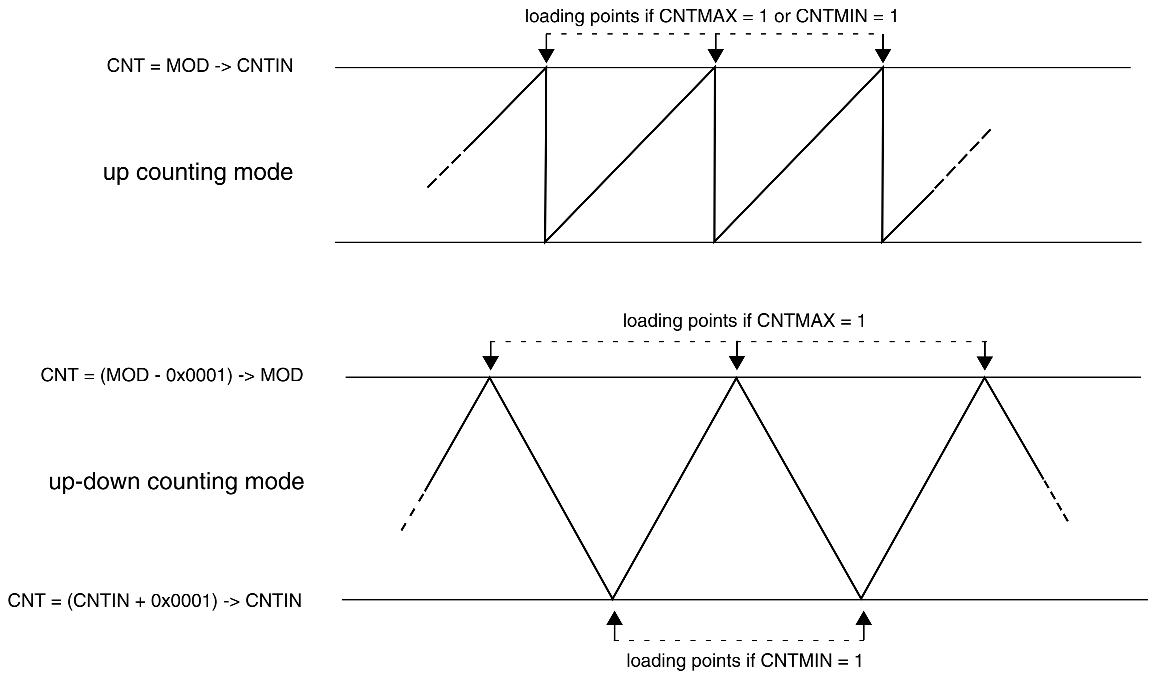

Figure 39-248. Boundary cycles and loading points

39.4.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

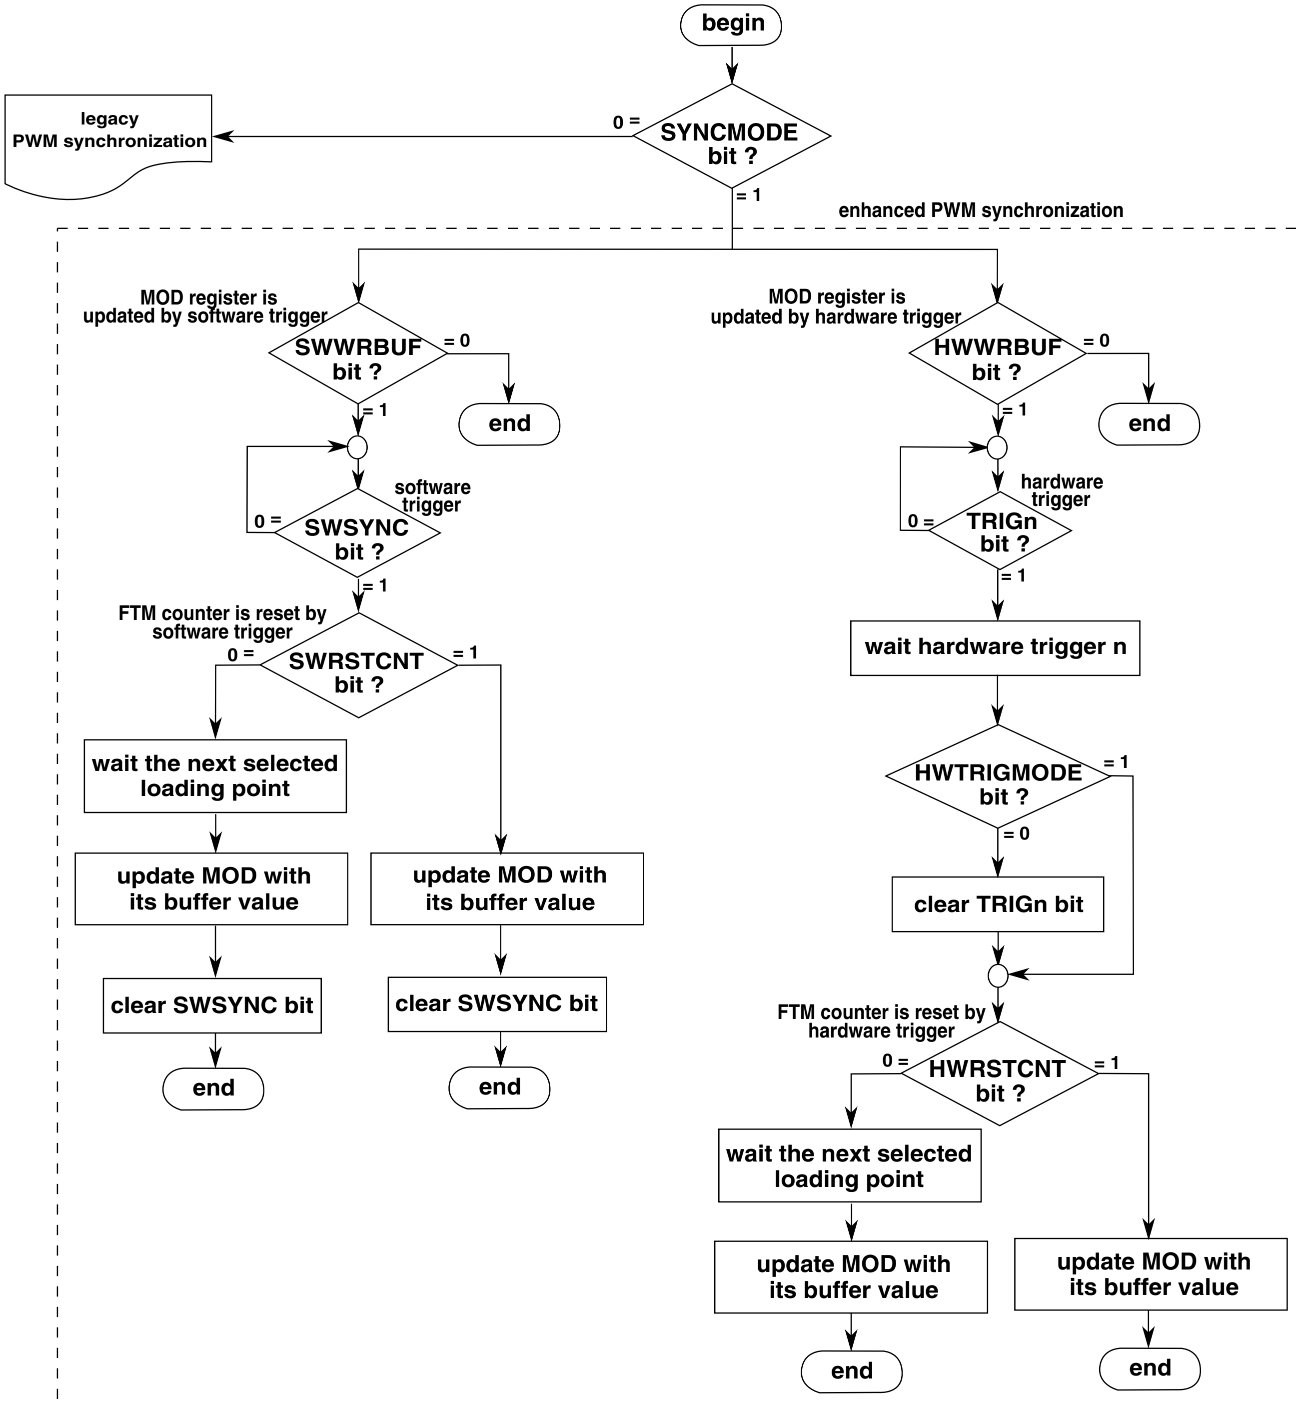

Figure 39-249. MOD register synchronization flowchart

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 0), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected

loading point. If the trigger event was a hardware trigger, then the trigger enable bit (TRIGn) is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

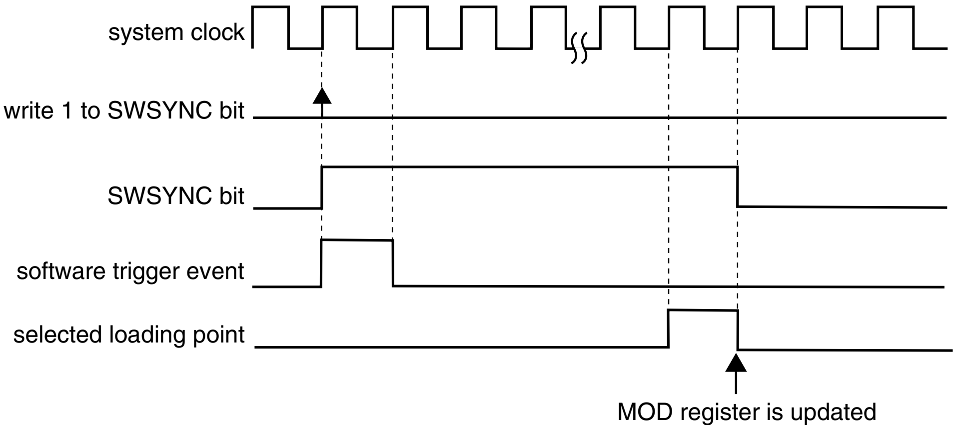

Figure 39-250. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 0), and software trigger was used

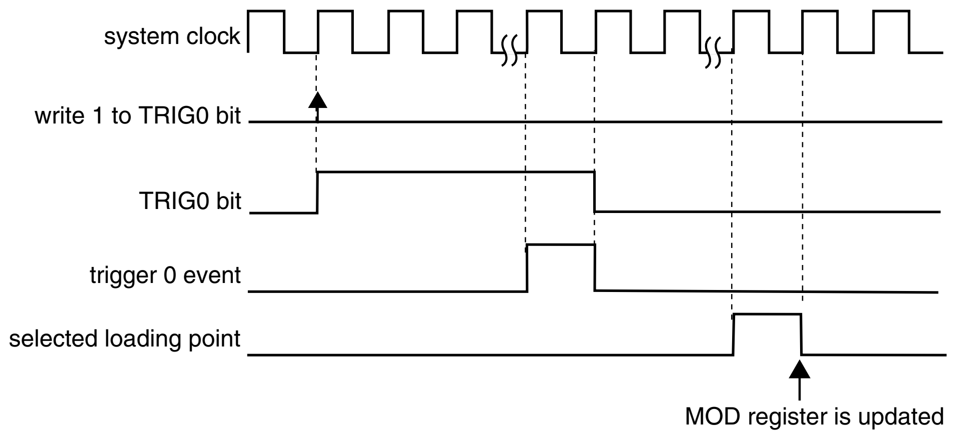

Figure 39-251. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 1), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

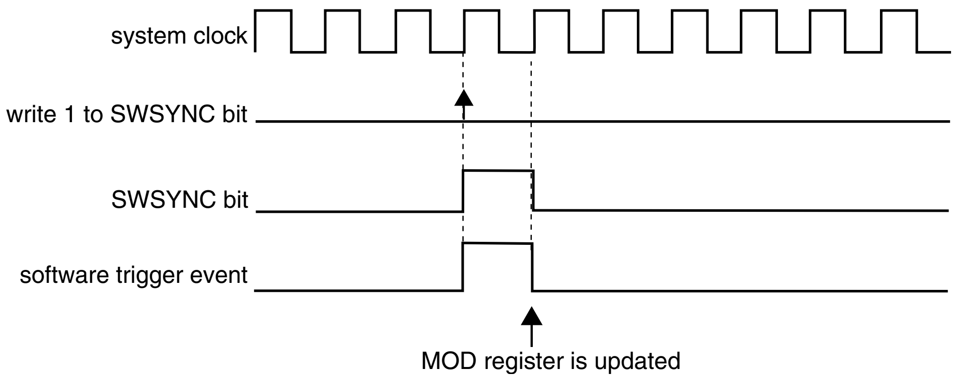

Figure 39-252. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used

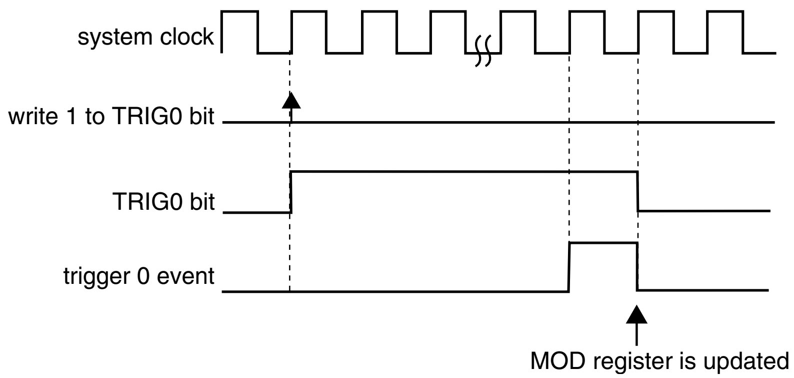

Figure 39-253. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

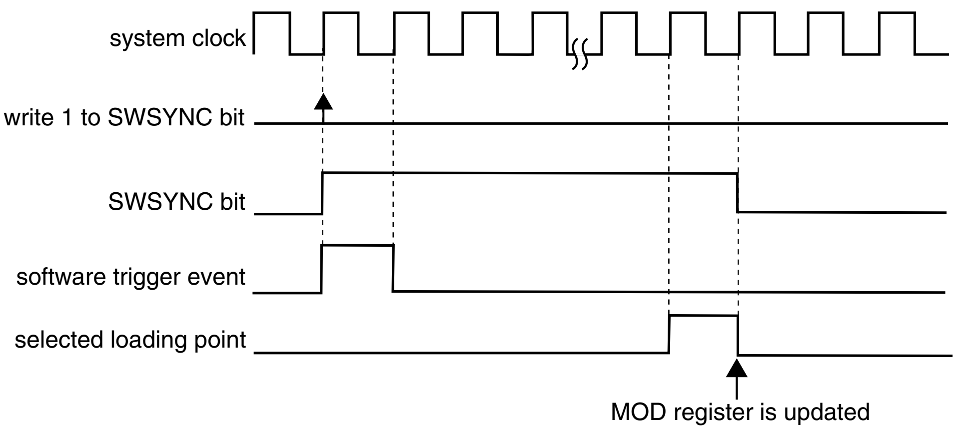

Figure 39-254. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)

39.4.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see MOD register synchronization.

39.4.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the MOD register synchronization. However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

39.4.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

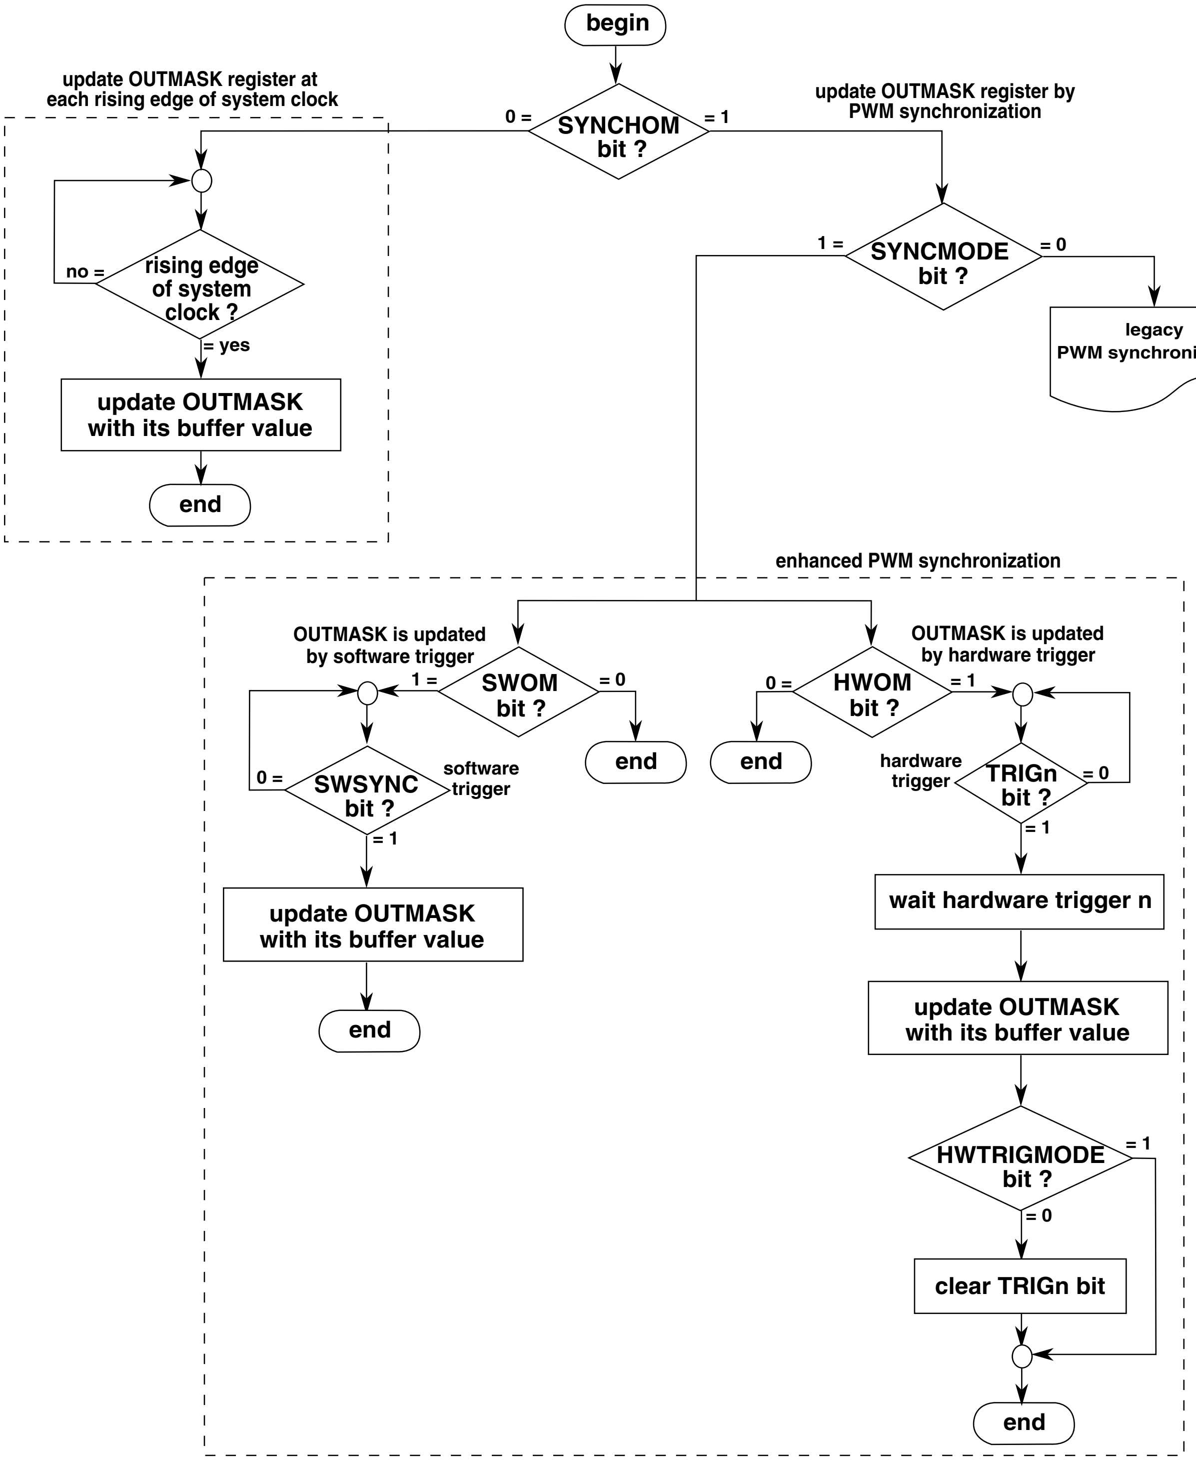

Figure 39-255. OUTMASK register synchronization flowchart

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

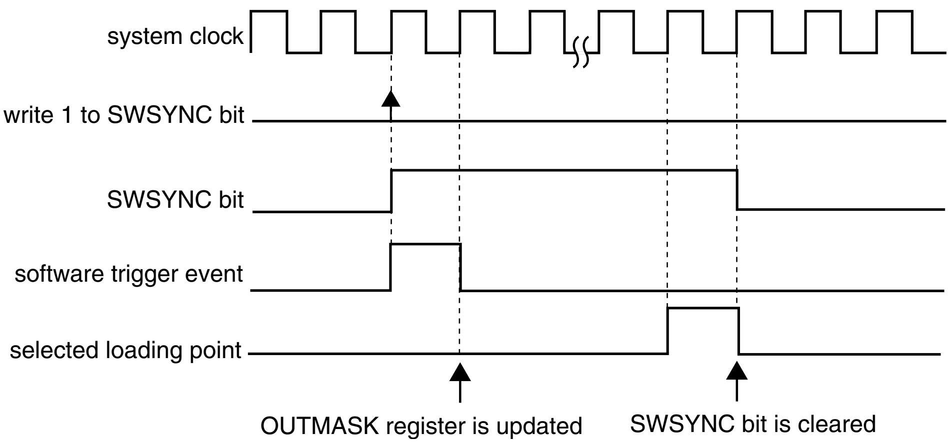

Figure 39-256. OUTMASK synchronization with (SYNCMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used

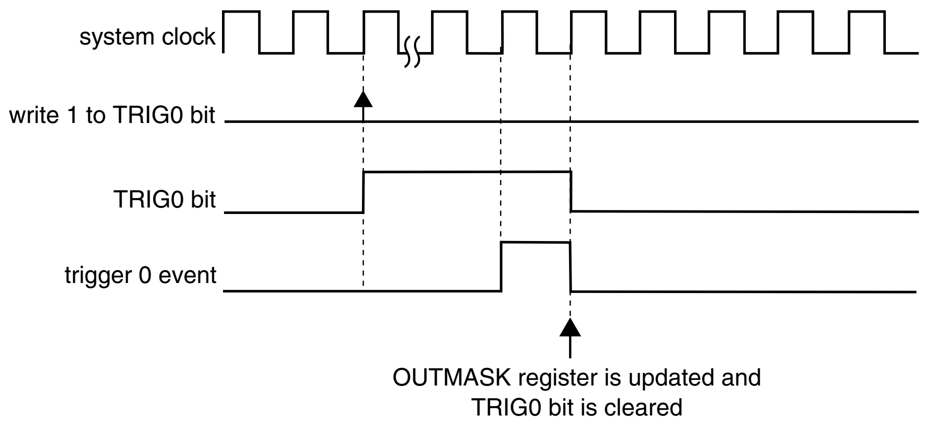

Figure 39-257. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to Hardware trigger. An example with a hardware trigger follows.

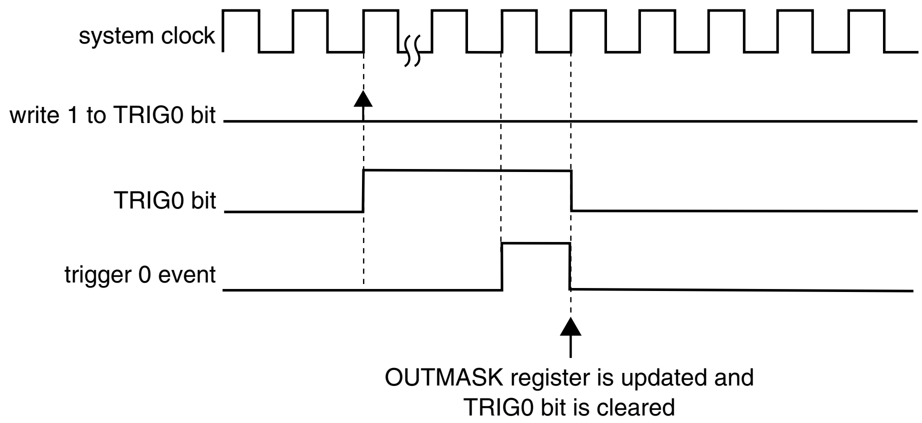

Figure 39-258. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used

39.4.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

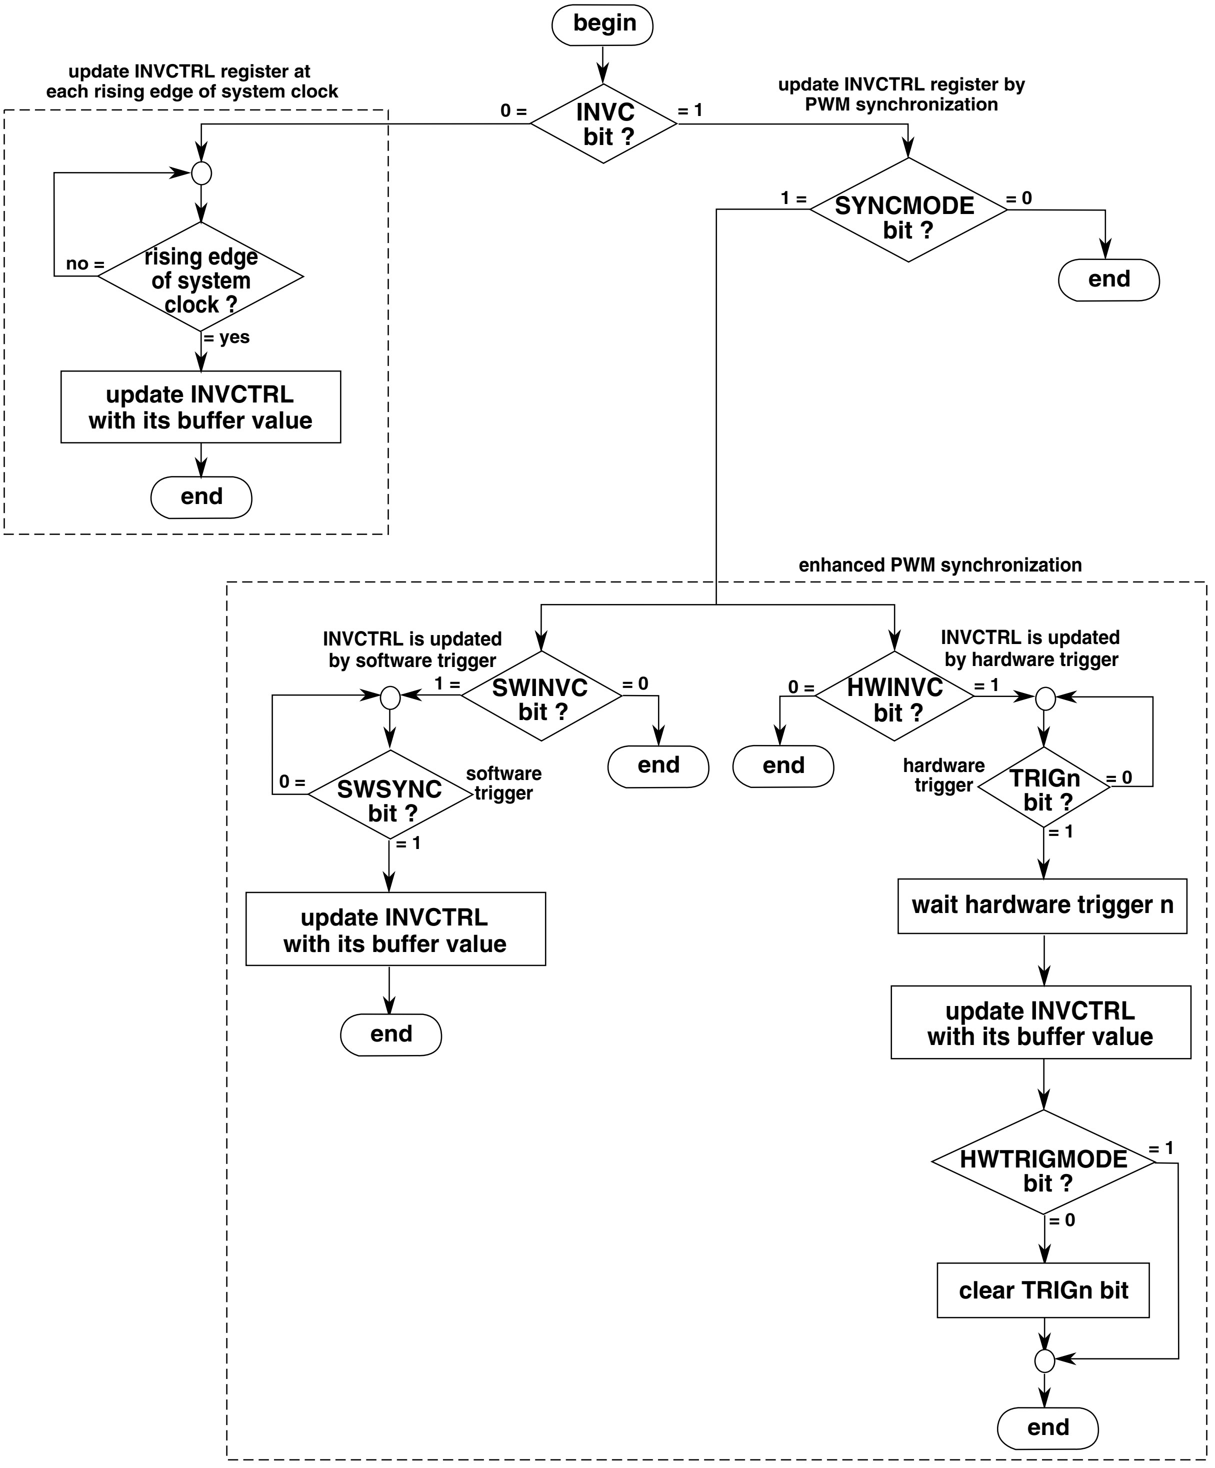

Figure 39-259. INVCTRL register synchronization flowchart

39.4.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

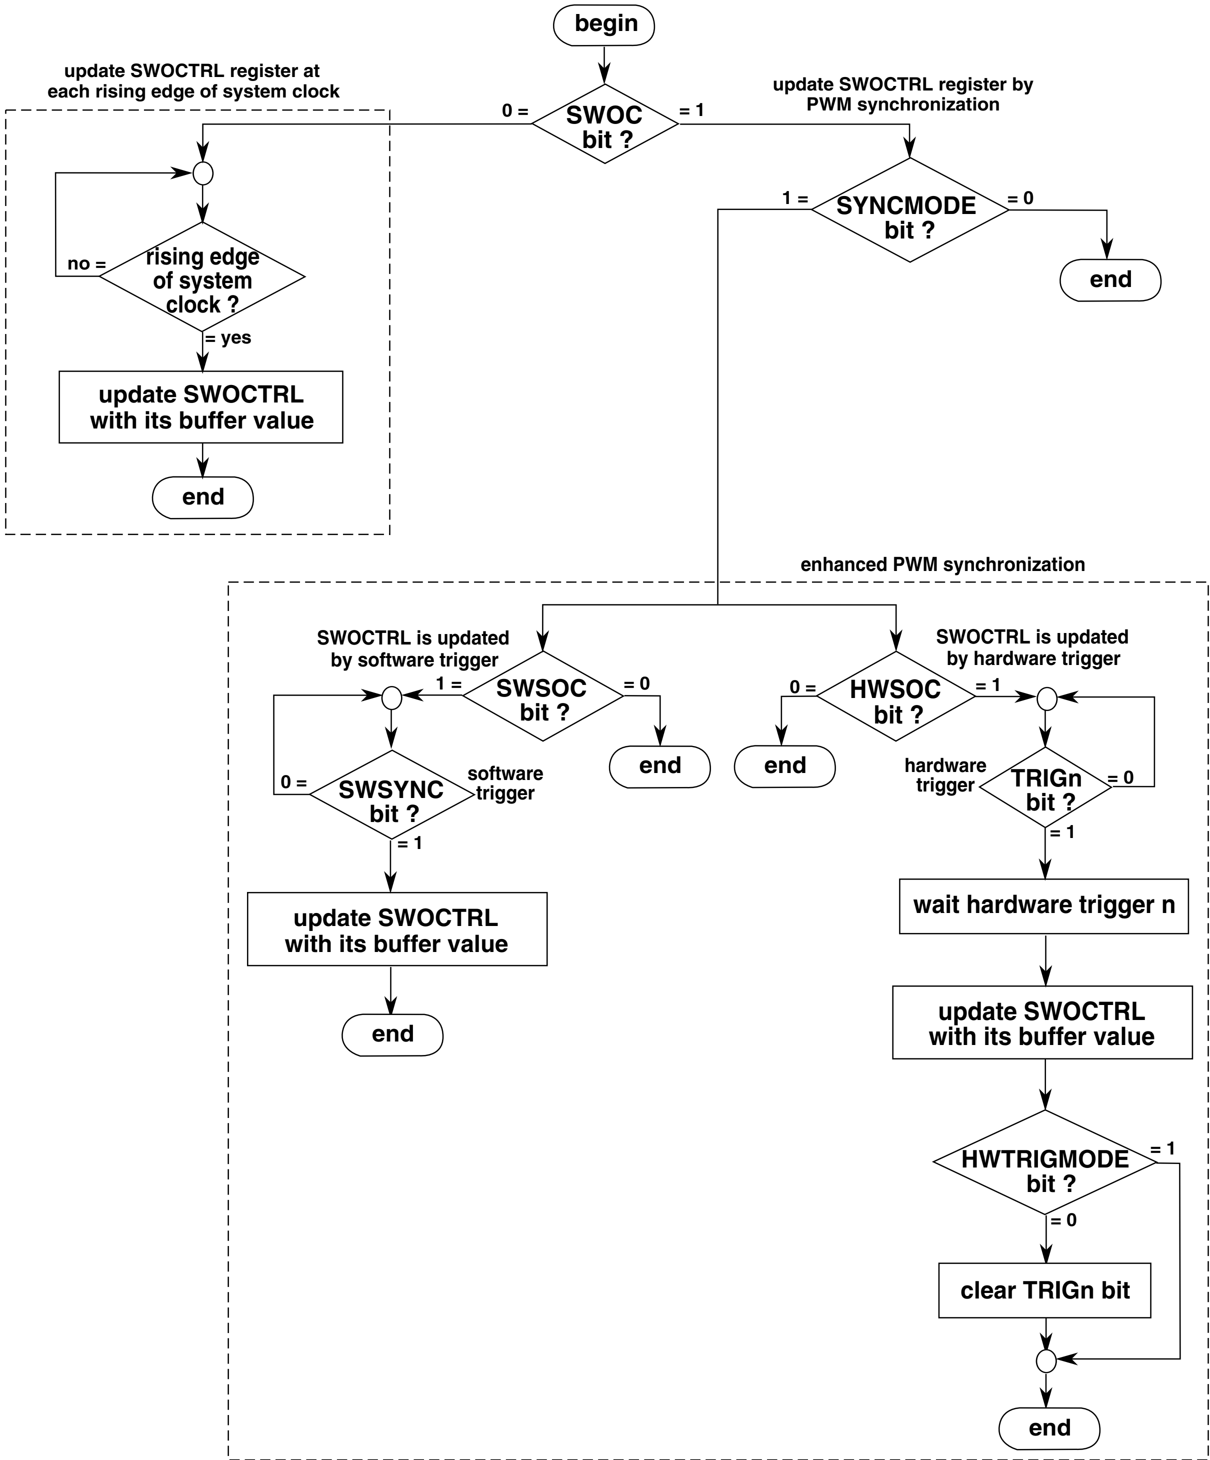

Figure 39-260. SWOCTRL register synchronization flowchart

39.4.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n +1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

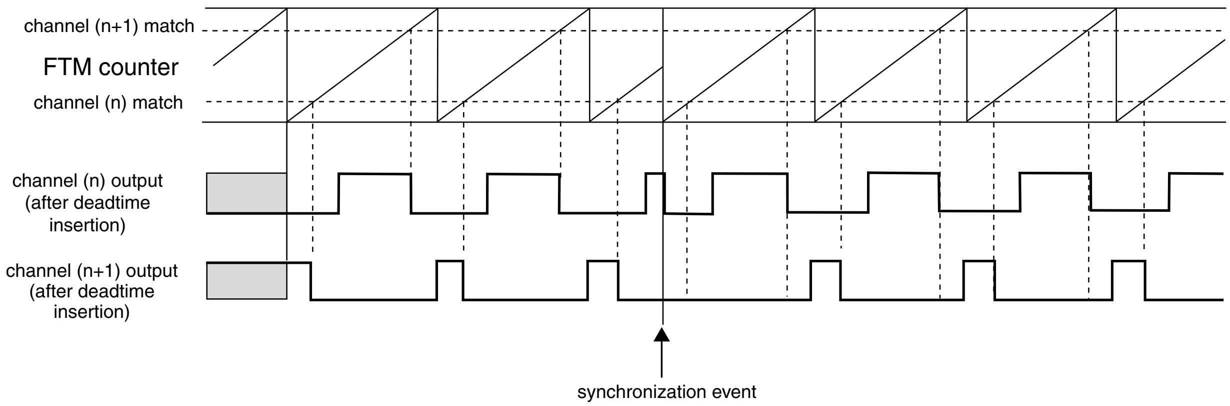

Figure 39-261. FTM counter synchronization

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

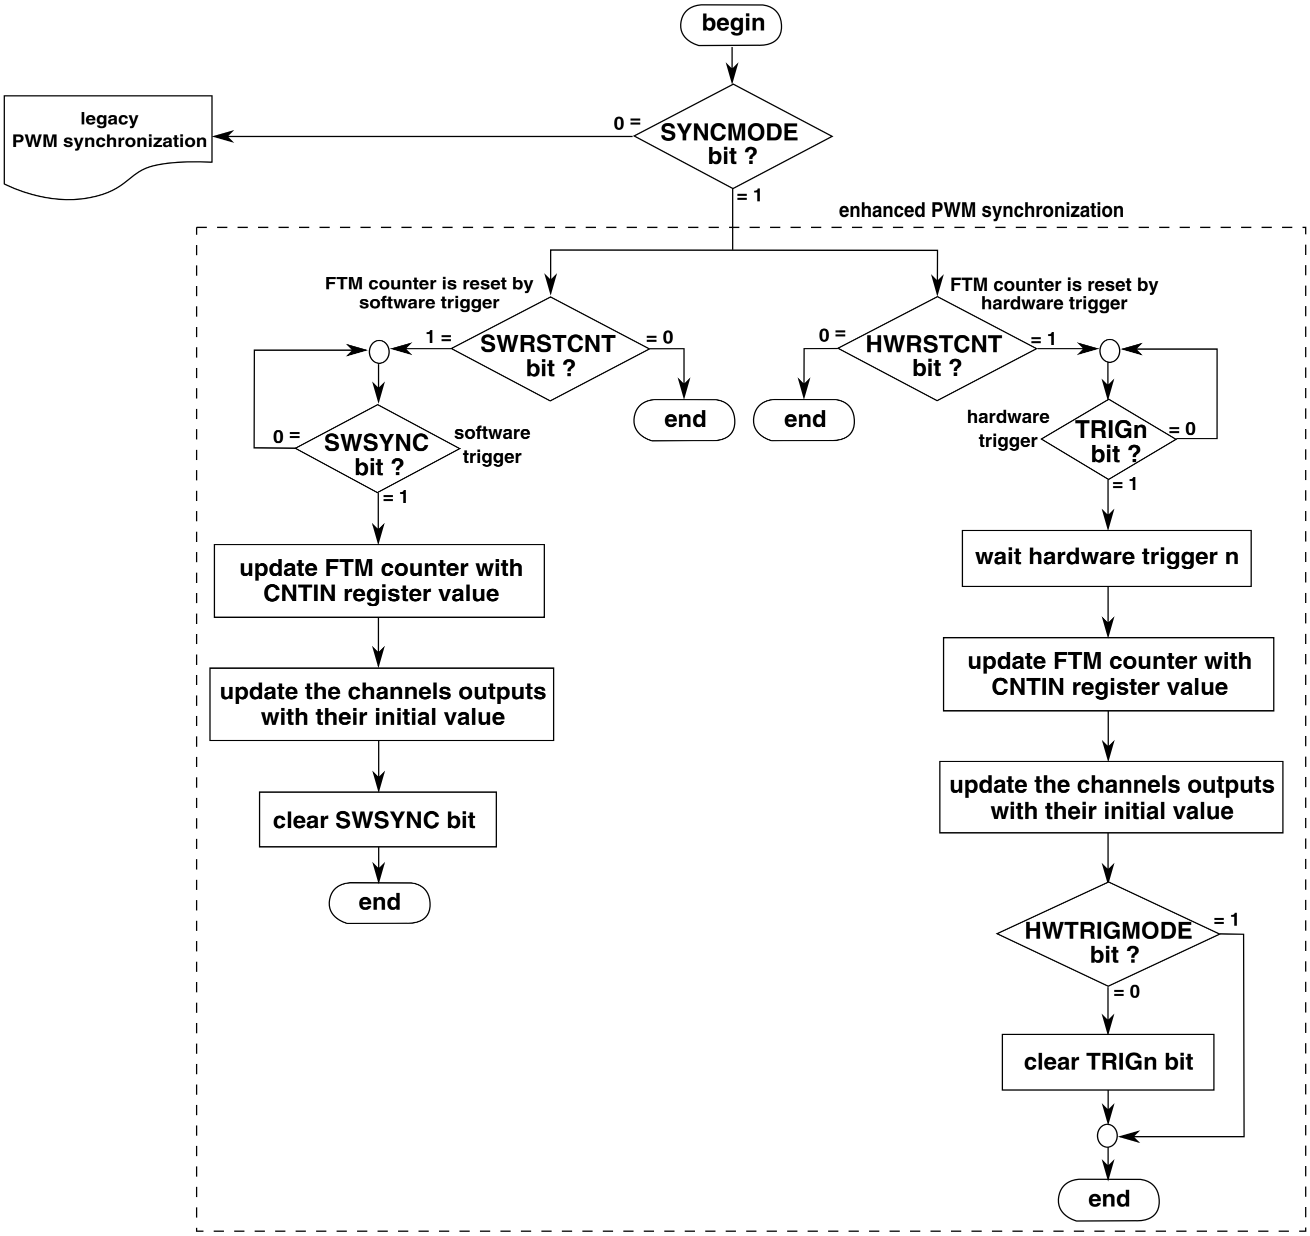

Figure 39-262. FTM counter synchronization flowchart

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

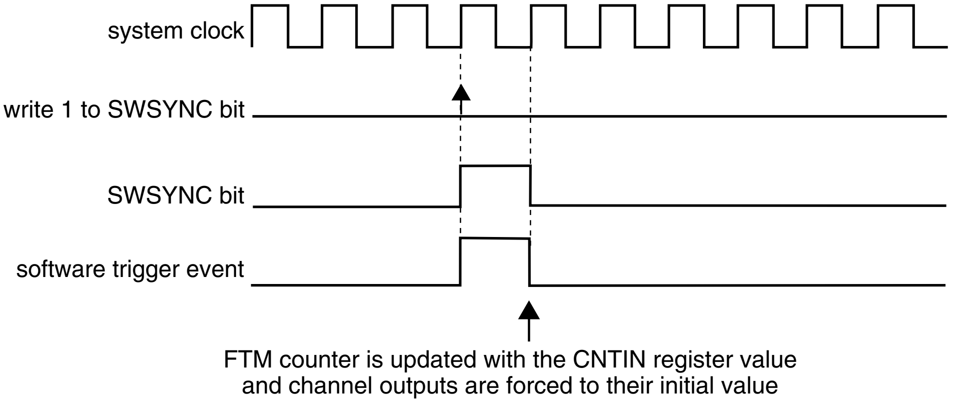

Figure 39-263. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used

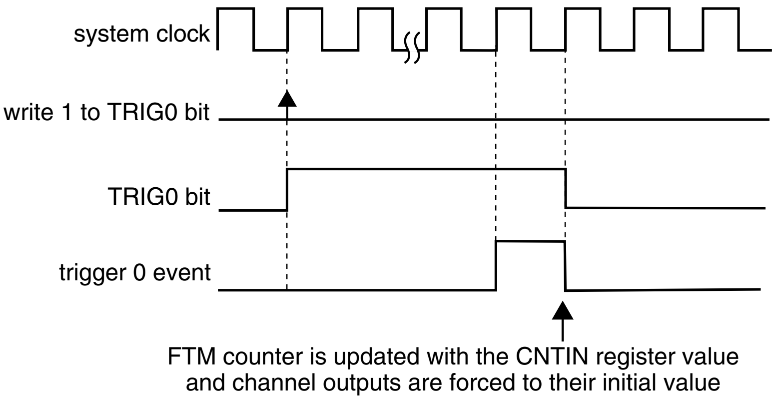

Figure 39-264. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to Hardware trigger.

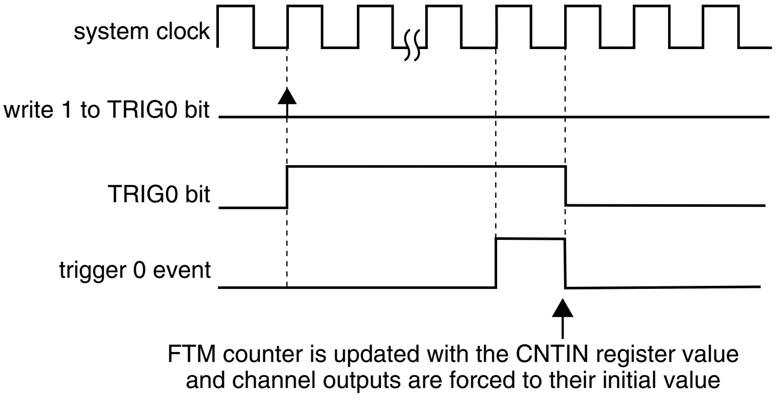

Figure 39-265. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used

39.4.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- FTMEN = 1
- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1
- COMP = 1
- CPWMS = 0, and
- INVm = 1 (where m represents a channel pair)

The INVm bit in INVCTRL register is updated with its buffer value according to INVCTRL register synchronization

In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

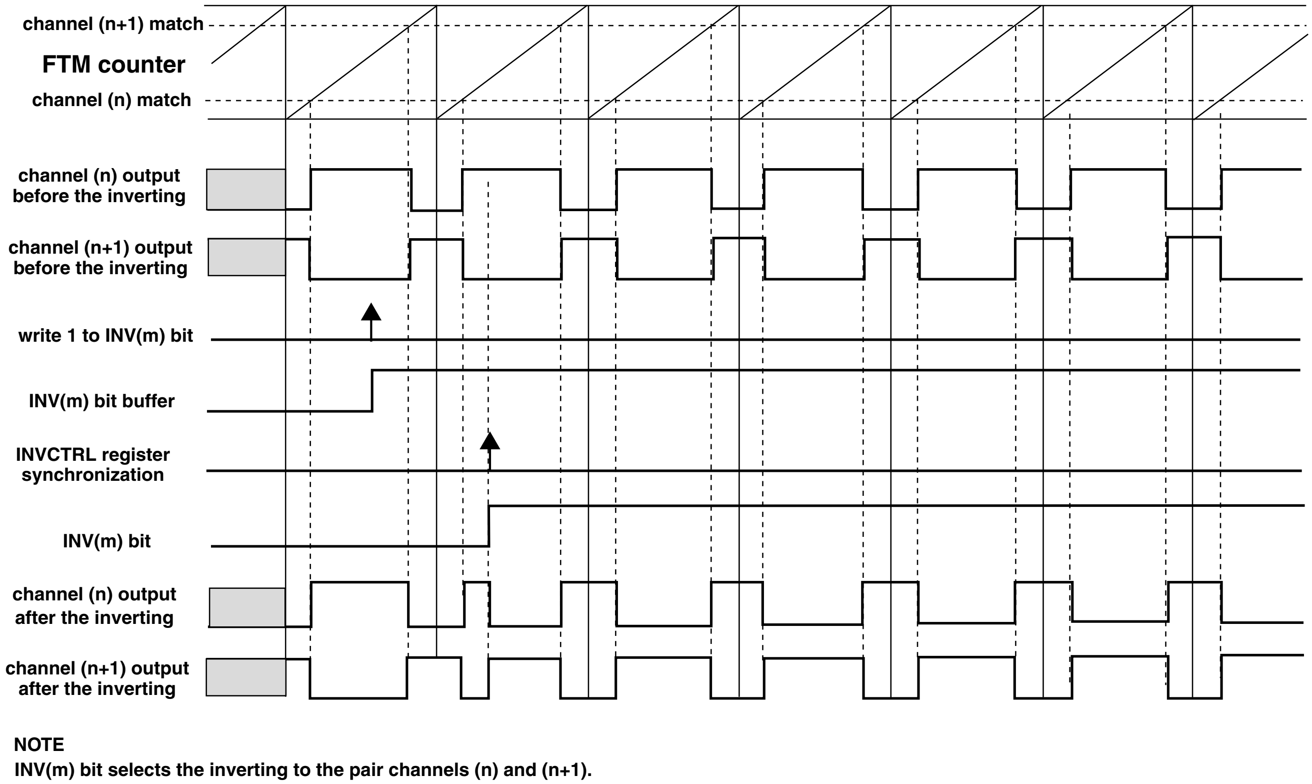

Figure 39-266. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode

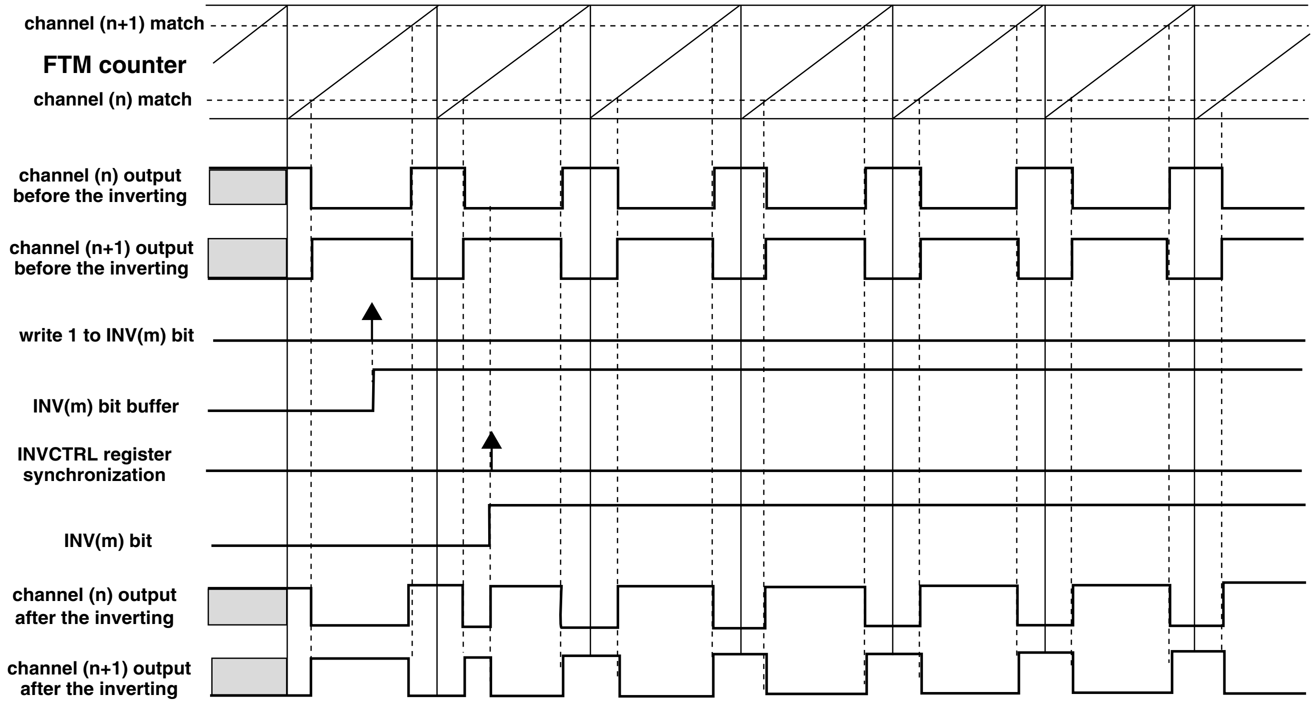
Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.



NOTE
INV(m) bit selects the inverting to the pair channels (n) and (n+1).

Figure 39-267. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode

Note

The inverting feature must be used only in Combine mode.

39.4.13 Software output control

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

The software output control is selected when:

- FTMEN = 1
- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1
- CPWMS = 0, and
- CHnOC = 1

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to SWOCTRL register synchronization.

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

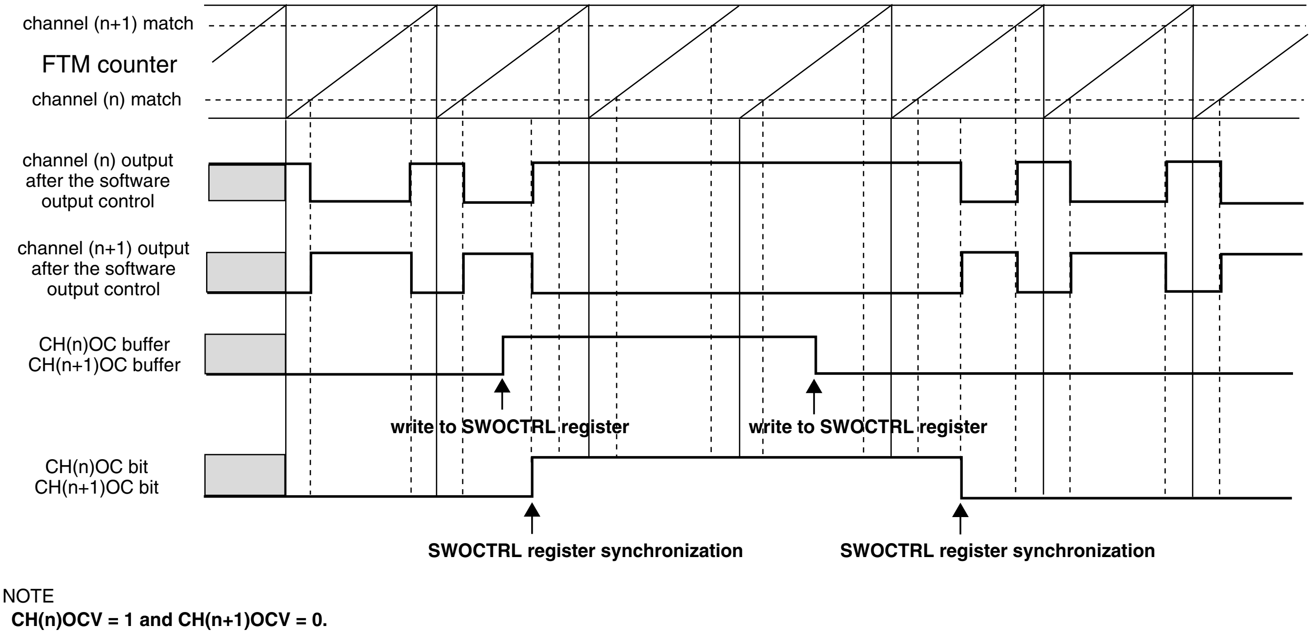


Figure 39-268. Example of software output control in Combine and Complementary mode

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

Table 39-306. Software ouput control behavior when (COMP = 0)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to one

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

Table 39-307. Software ouput control behavior when (COMP = 1)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to zero

Note

- The software output control feature must be used only in Combine mode.
- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n +1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

39.4.14 Deadtime insertion

The deadtime insertion is enabled when (DTEN = 1) and (DTVAL[5:0] is non- zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTPS[1:0] bits define the prescaler for the system clock and the DTVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If POL(n) = 0, POL(n+1) = 0, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If POL(n) = 1, POL(n+1) = 1, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n +1) output is cleared.

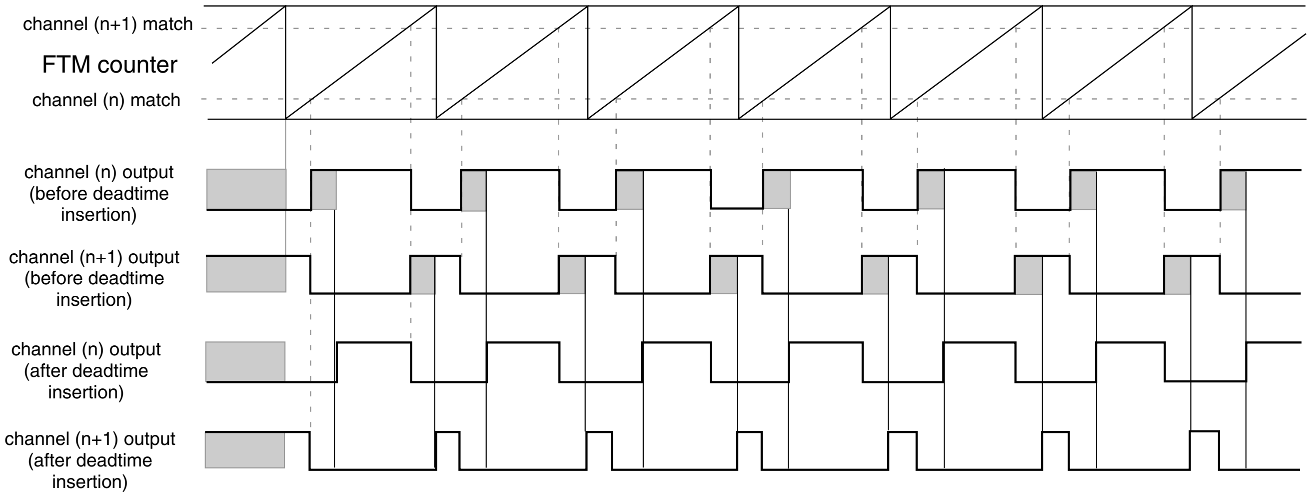

Figure 39-269. Deadtime insertion with ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0

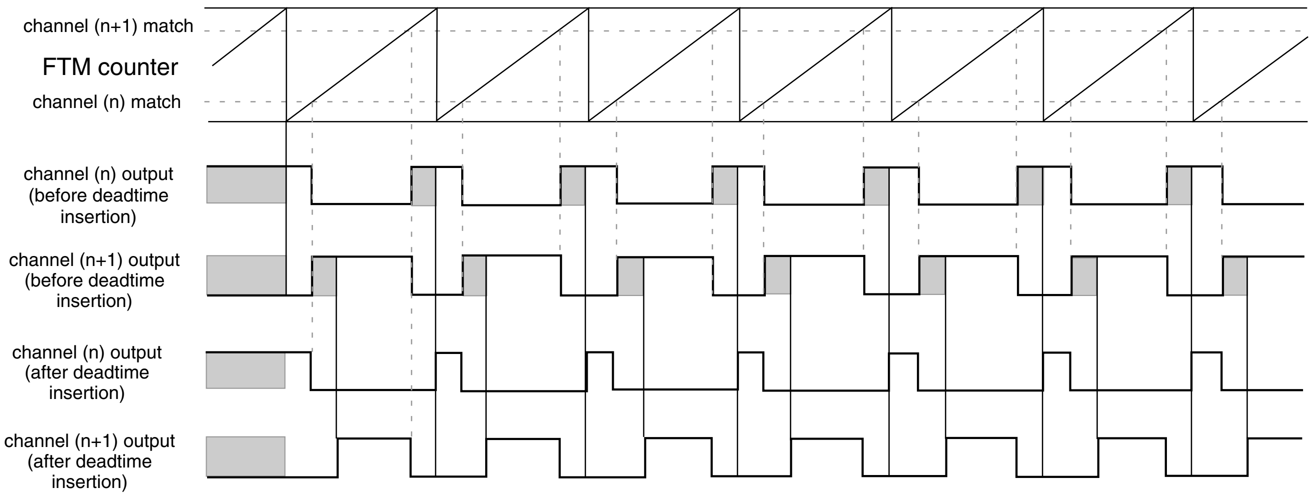

Figure 39-270. Deadtime insertion with ELSnB:ELSnA = X:1, POL(n) = 0, and POL(n+1) = 0

NOTE

The deadtime feature must be used only in Combine and Complementary modes.

39.4.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ((C(n +1)V – C(n)V) × system clock), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ((MOD – CNTIN + 1 – (C(n+1)V – C(n)V)) × system clock), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

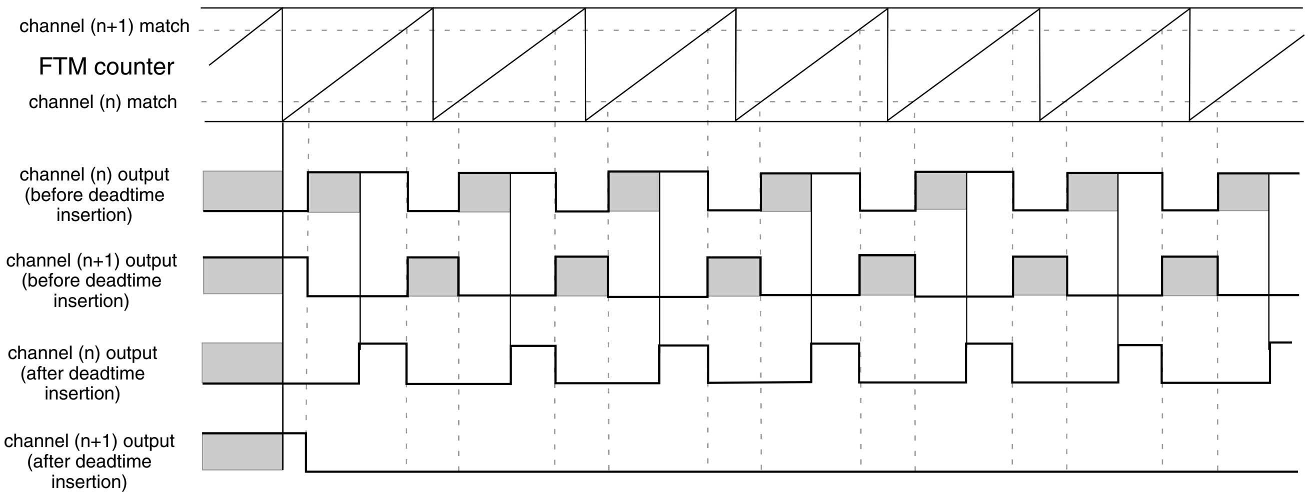

Figure 39-271. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle

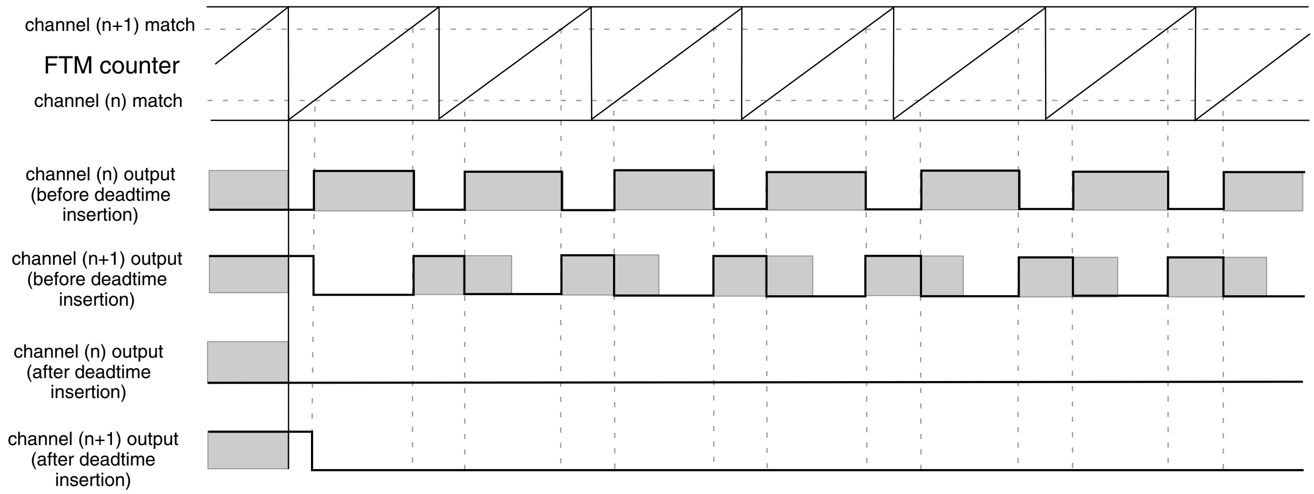

Figure 39-272. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle

39.4.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see OUTMASK register synchronization.

If CHnOM = 1, then the channel (n) output is forced to its inactive state (POLn bit value). If CHnOM = 0, then the channel (n) output is unaffected by the output mask. See the following figure.

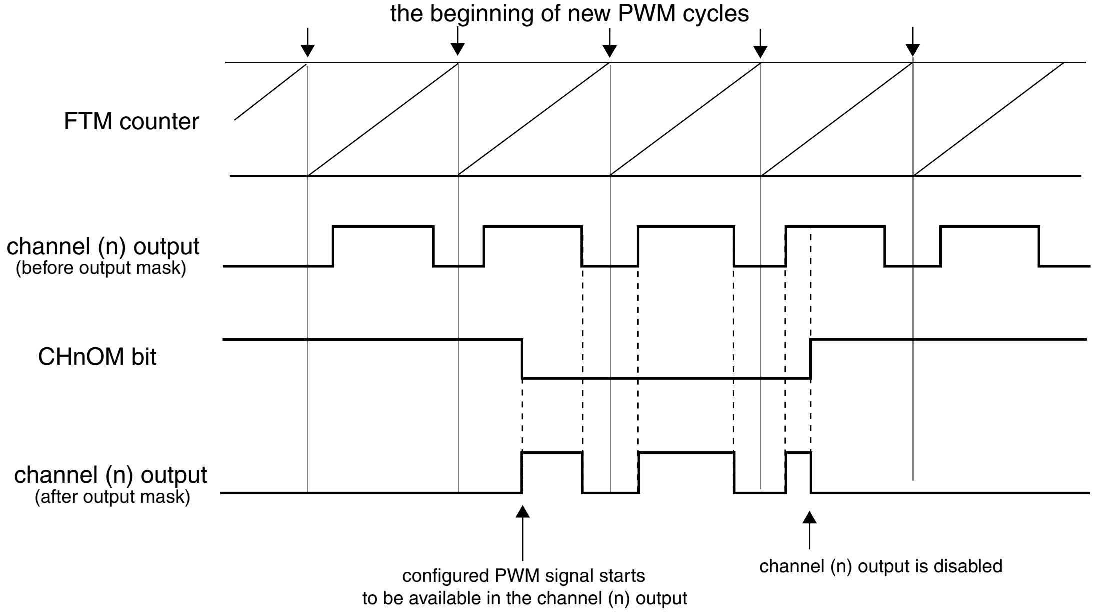

Figure 39-273. Output mask with POLn = 0

The following table shows the output mask result before the polarity control.

Table 39-308. Output mask result for channel (n) before the polarity control

CHnOM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	

Note

The output mask feature must be used only in Combine mode.

39.4.16 Fault control

The fault control is enabled if (FTMEN = 1) and (FAULTM[1:0] ≠ 0:0).

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

First, each fault input signal is synchronized by the system clock; see the synchronizer block in the following figure. Following synchronization, the fault input n signal enters the filter block. When there is a state change in the fault input n signal, the 5-bit counter

is reset and starts counting up. As long as the new state is stable on the fault input n, the counter continues to increment. If the 5-bit counter overflows, that is, the counter exceeds the value of the FFVAL[3:0] bits, the new fault input n value is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the fault input n signal before validation (counter overflow), the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by FFVAL[3:0] bits (× system clock) is regarded as a glitch and is not passed on to the edge detector.

The fault input n filter is disabled when the FFVAL[3:0] bits are zero or when FAULTnEN = 0. In this case, the fault input n signal is delayed 2 rising edges of the system clock and the FAULTFn bit is set on 3th rising edge of the system clock after a rising edge occurs on the fault input n.

If FFVAL[3:0] ≠ 0000 and FAULTnEN = 1, then the fault input n signal is delayed (3 + FFVAL[3:0]) rising edges of the system clock, that is, the FAULTFn bit is set (4 + FFVAL[3:0]) rising edges of the system clock after a rising edge occurs on the fault input n.

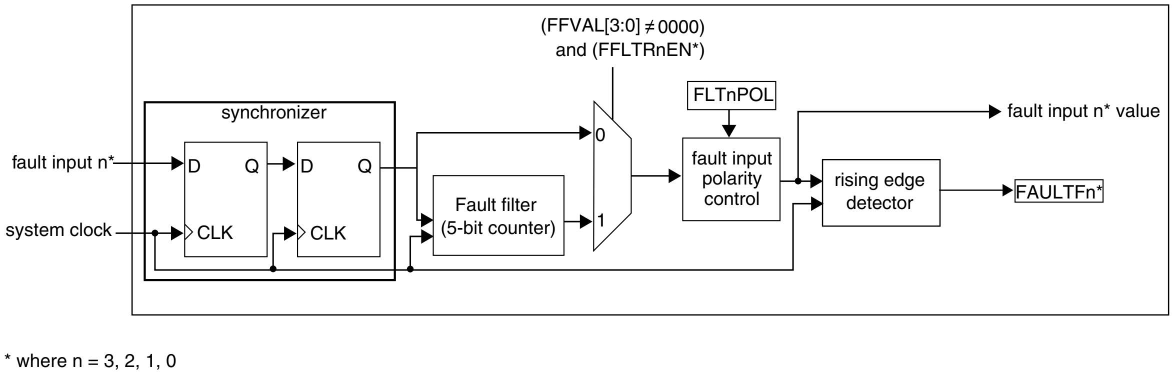

Figure 39-274. Fault input n control block diagram

If the fault control and fault input n are enabled and a rising edge at the fault input n signal is detected, a fault condition has occurred and the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

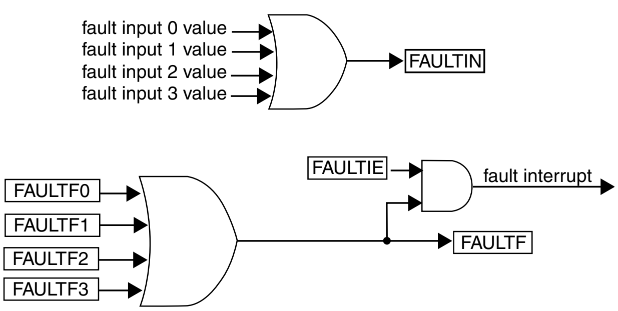

Figure 39-275. FAULTF and FAULTIN bits and fault interrupt

If the fault control is enabled (FAULTM[1:0] ≠ 0:0), a fault condition has occurred and (FAULTEN = 1), then outputs are forced to their safe values:

- Channel (n) output takes the value of POL(n)
- Channel (n+1) takes the value of POL(n+1)

The fault interrupt is generated when (FAULTF = 1) and (FAULTIE = 1). This interrupt request remains set until:

- Software clears the FAULTF bit by reading FAULTF bit as 1 and writing 0 to it
- Software clears the FAULTIE bit
- A reset occurs

Note

The fault control must be used only in Combine mode.

39.4.16.1 Automatic fault clearing

If the automatic fault clearing is selected (FAULTM[1:0] = 1:1), then the channels output disabled by fault control is again enabled when the fault input signal (FAULTIN) returns to zero and a new PWM cycle begins. See the following figure.

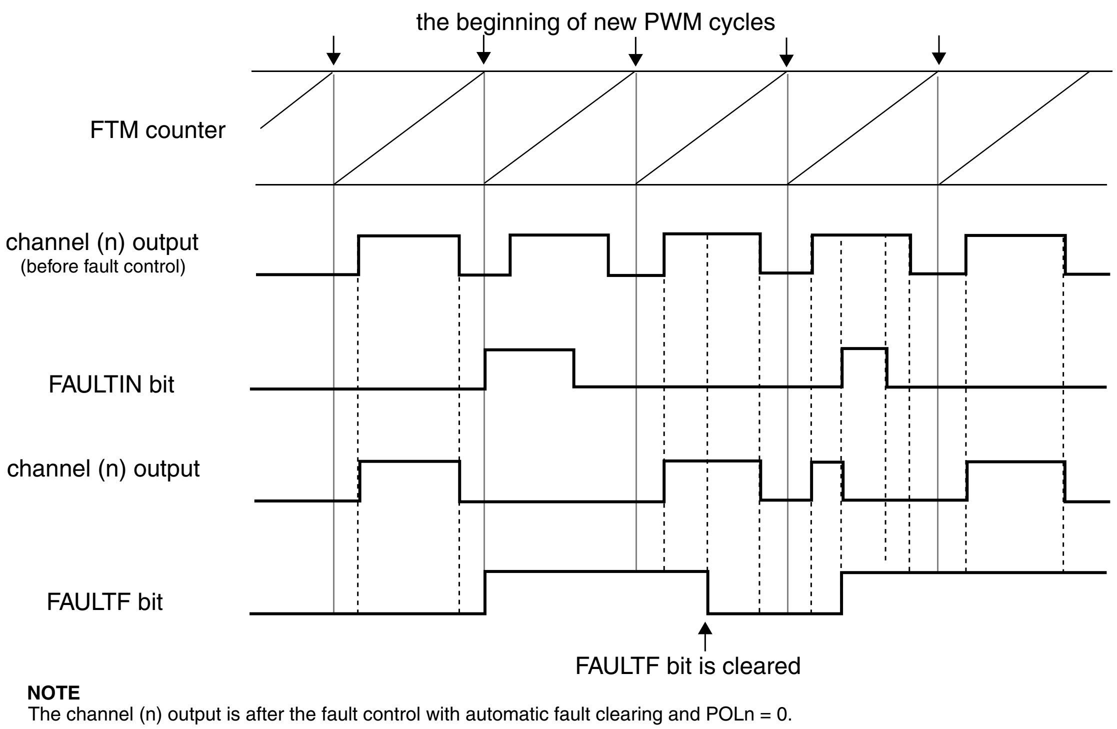

Figure 39-276. Fault control with automatic fault clearing

39.4.16.2 Manual fault clearing

If the manual fault clearing is selected (FAULTM[1:0] = 0:1 or 1:0), then the channels output disabled by fault control is again enabled when the FAULTF bit is cleared and a new PWM cycle begins. See the following figure.

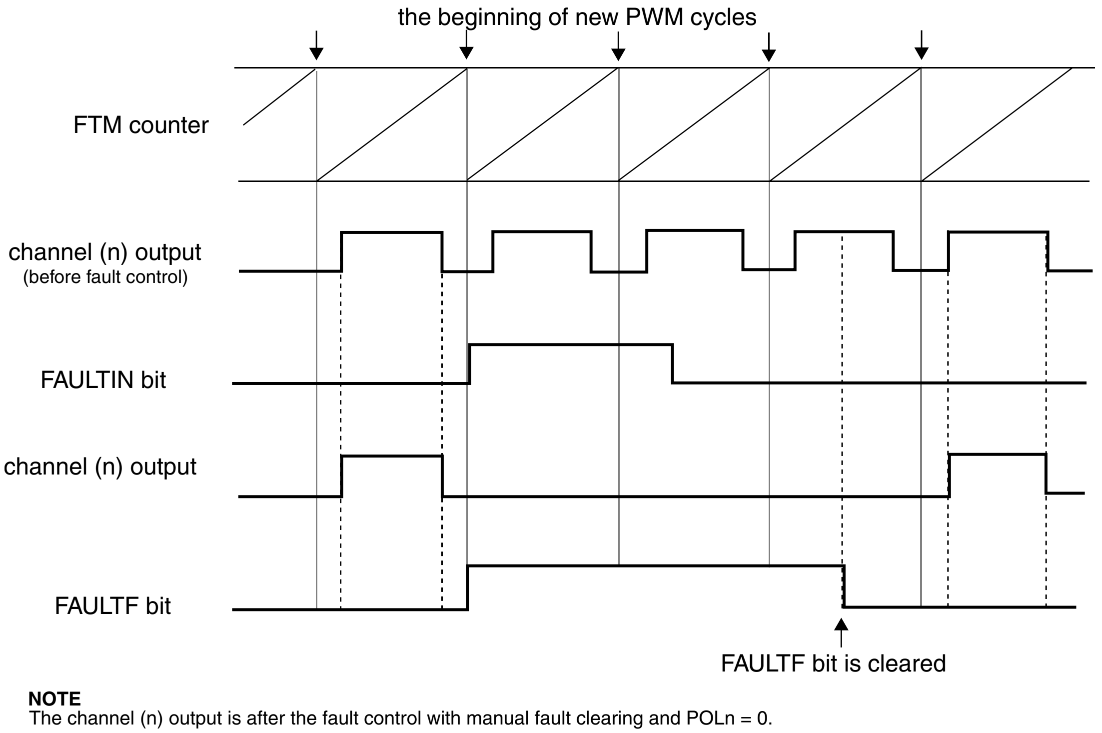

Figure 39-277. Fault control with manual fault clearing

39.4.16.3 Fault inputs polarity control

The FLTjPOL bit selects the fault input j polarity, where j = 0, 1, 2, 3:

- If FLTjPOL = 0, the fault j input polarity is high, so the logical one at the fault input j indicates a fault.
- If FLTjPOL = 1, the fault j input polarity is low, so the logical zero at the fault input j indicates a fault.

39.4.17 Polarity control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

Note

The polarity control must be used only in Combine mode.

39.4.18 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

Table 39-309. Initialization behavior when (COMP = 0 and DTEN = 0)

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	0	is forced to zero	is forced to zero
0	1	is forced to zero	is forced to one
1	0	is forced to one	is forced to zero
1	1	is forced to one	is forced to one

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

Table 39-310. Initialization behavior when (COMP = 1 or DTEN = 1)

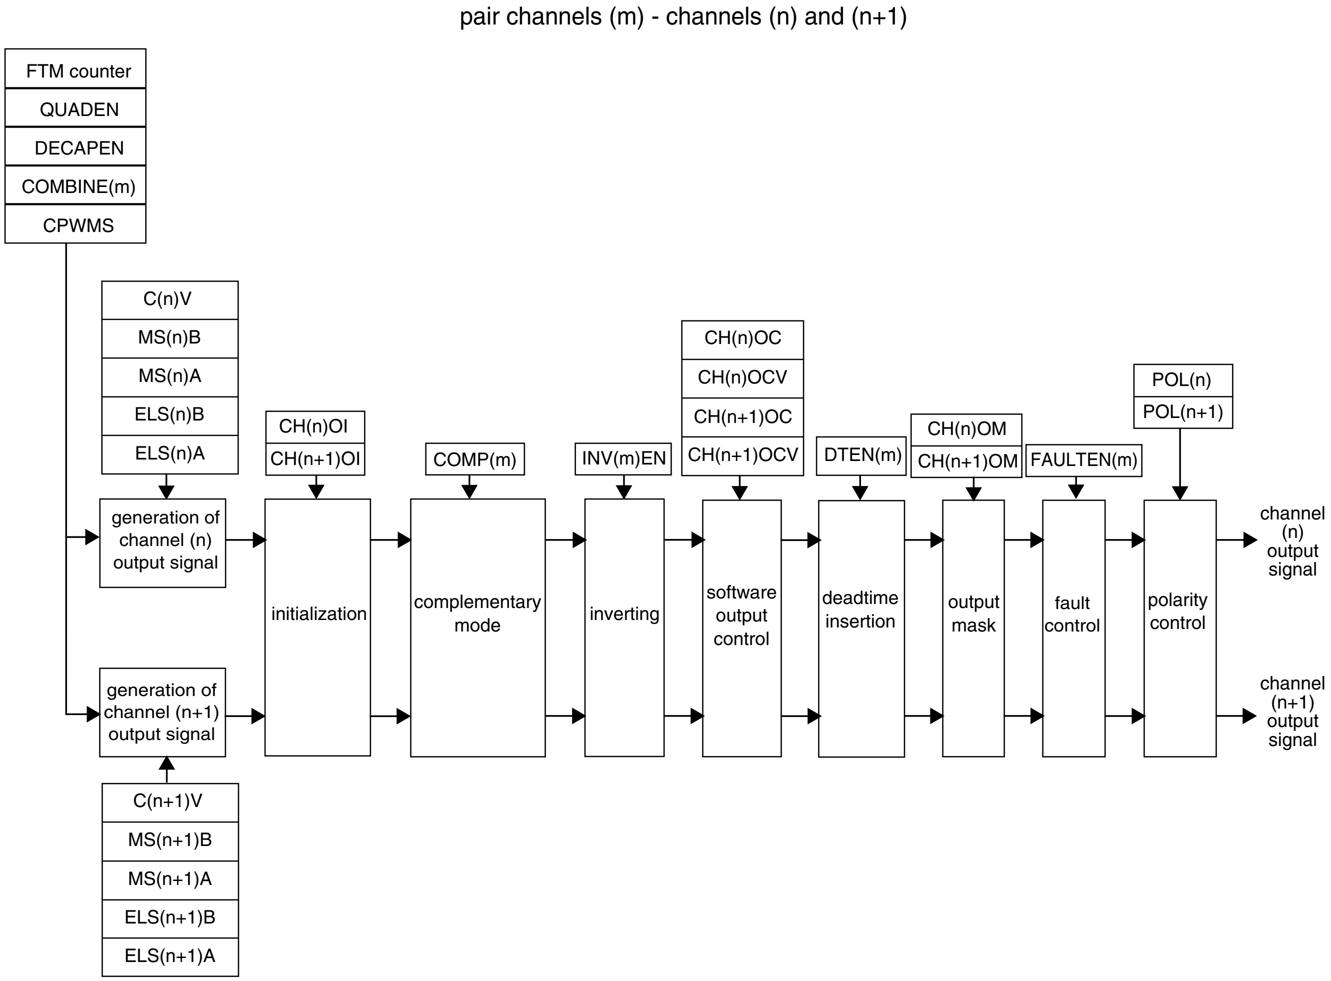
CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	X	is forced to zero	is forced to one
1	X	is forced to one	is forced to zero

Note

The initialization feature must be used only in Combine mode and with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

39.4.19 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.



NOTE
The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

Figure 39-278. Priority of the features used at the generation of channels (n) and (n+1) outputs signals

Note

The Initialization feature must not be used with Inverting and Software output control features.

39.4.20 Channel trigger output

If CHjTRIG = 1, where j = 0, 1, 2, 3, 4, or 5, then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal that is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

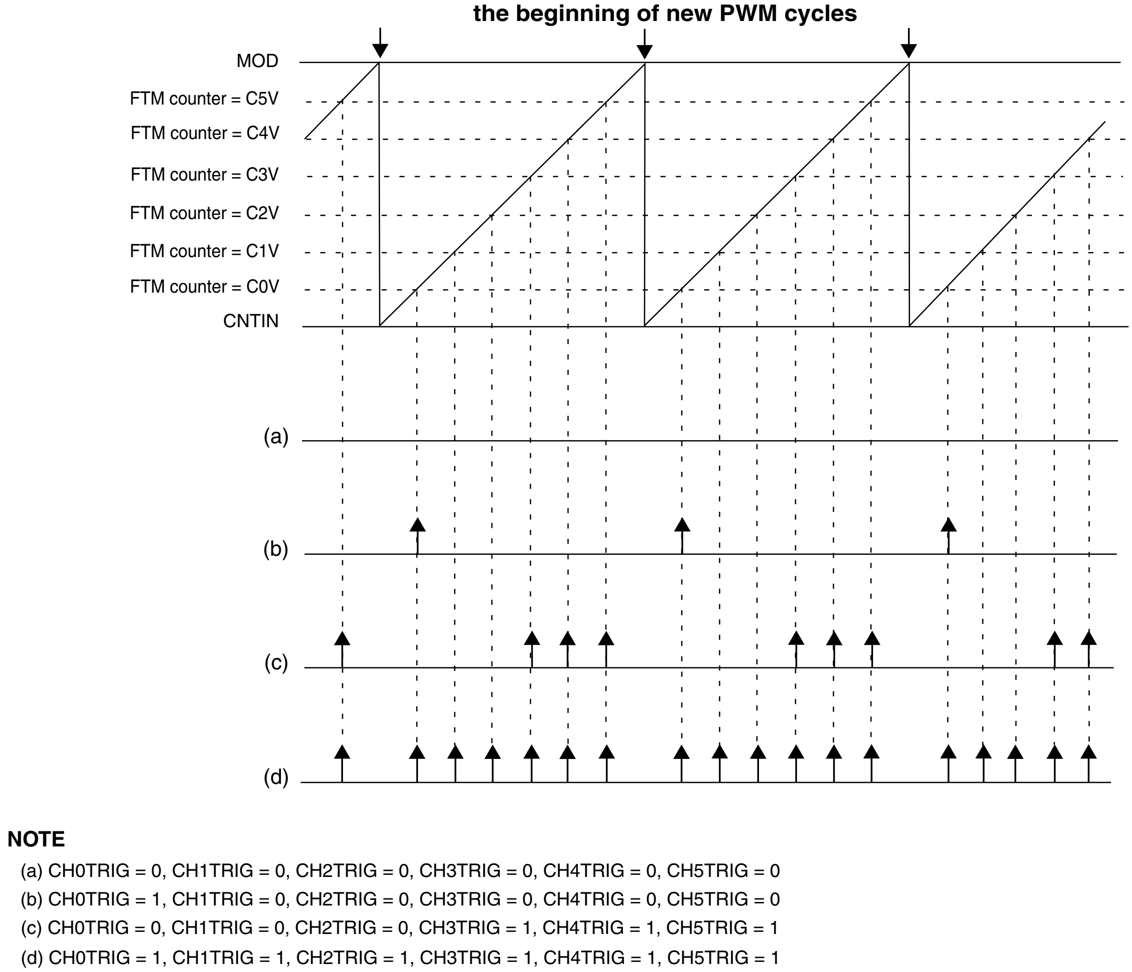


Figure 39-279. Channel match trigger

Note

The channel match trigger must be used only in Combine mode.

39.4.21 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.

- When there is a write to CNT register.
- When there is the FTM counter synchronization.
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.

The following figures show these cases.

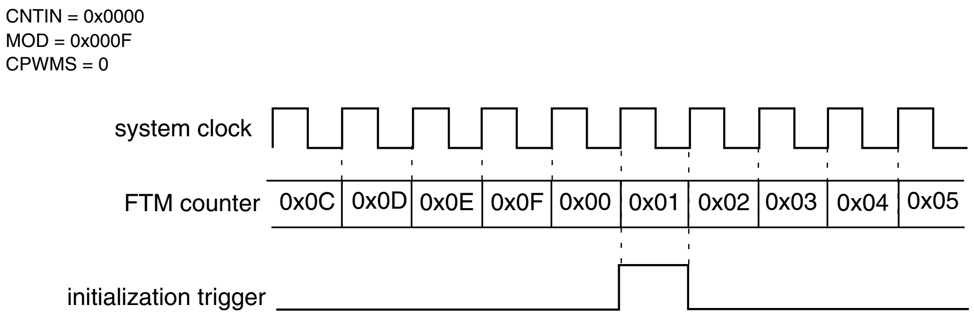

Figure 39-280. Initialization trigger is generated when the FTM counting achieves the CNTIN register value

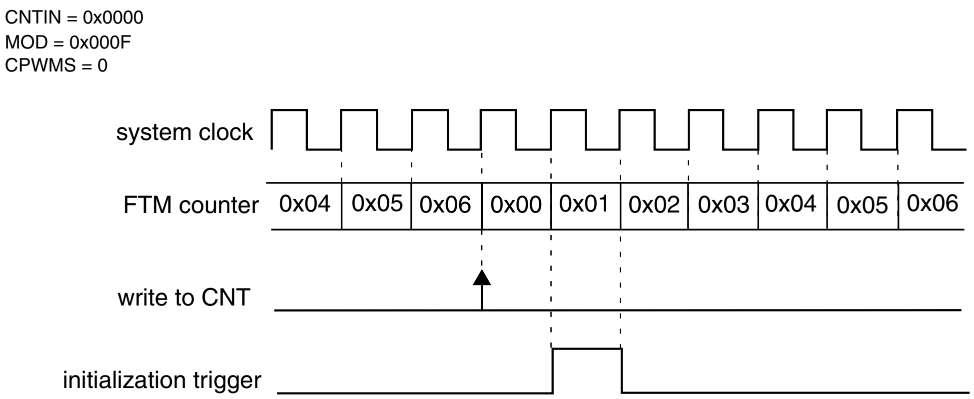

Figure 39-281. Initialization trigger is generated when there is a write to CNT register

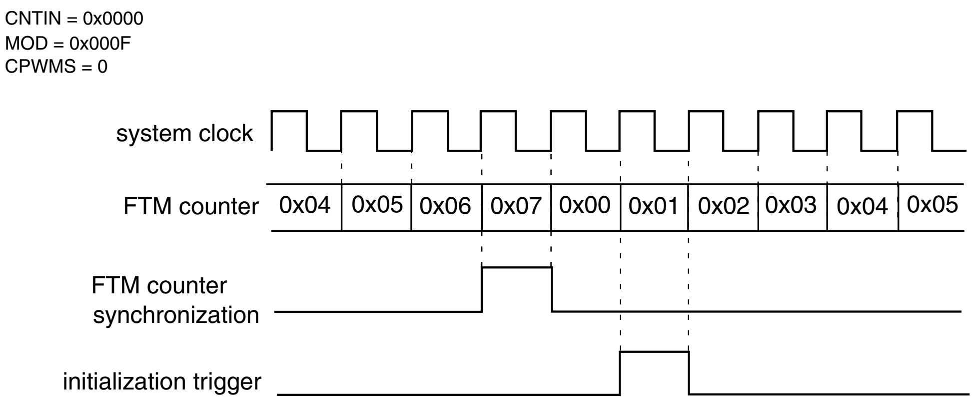

Figure 39-282. Initialization trigger is generated when there is the FTM counter synchronization

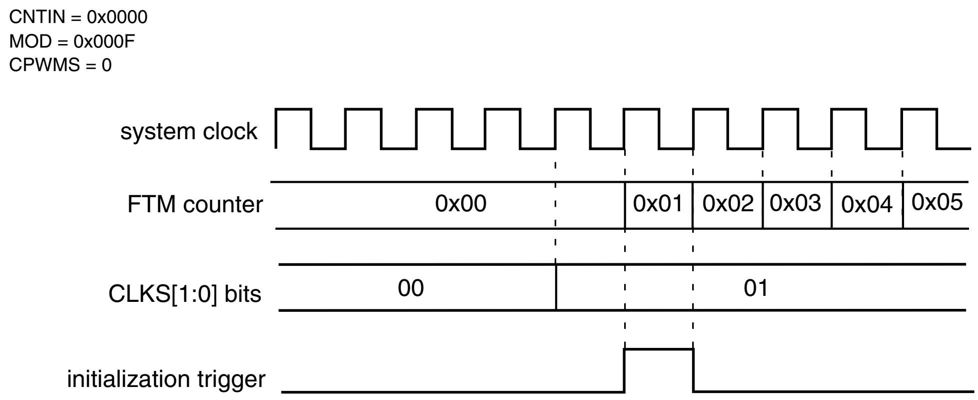

Figure 39-283. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits

The initialization trigger output provides a trigger signal that is used for on-chip modules.

Note

The initialization trigger must be used only in Combine mode.

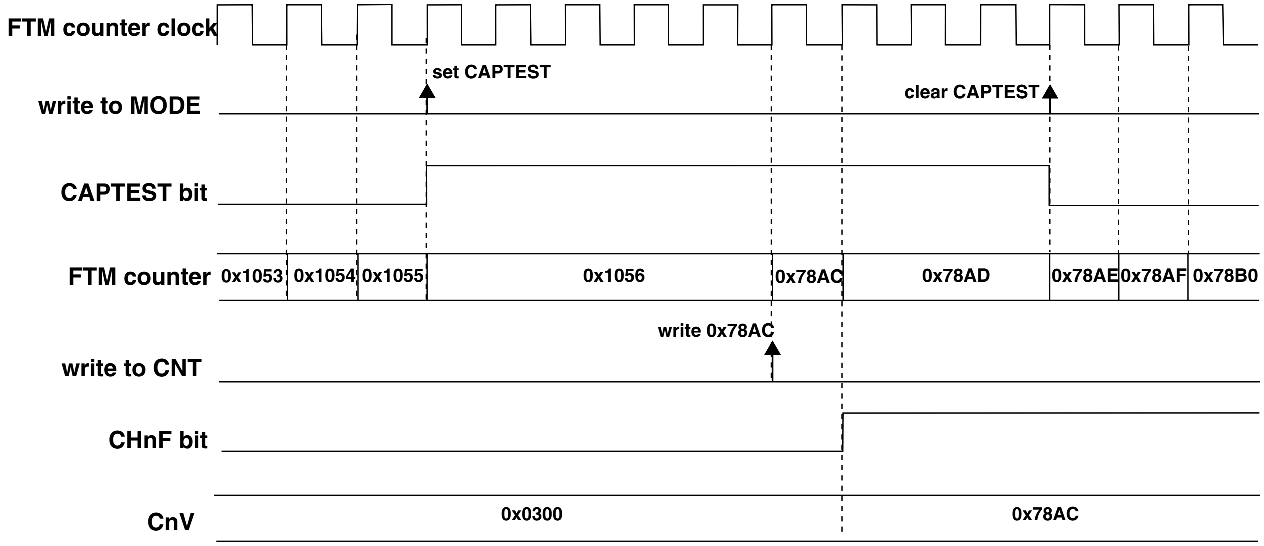
39.4.22 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for Input Capture mode and FTM counter must be configured to the Up counting.

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.



NOTE
- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

Figure 39-284. Capture Test mode

39.4.23 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

Table 39-311. Channel DMA transfer request

DMA	CHnIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHnF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHnF = 1).	The channel interrupt is not generated.

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

Table 39-312. Clear CHnF bit when DMA = 1

CHnIE	How CHnF Bit Can Be Cleared
0	CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit.
1	CHnF bit is cleared when the channel DMA transfer is done.

39.4.24 Dual Edge Capture mode

The Dual Edge Capture mode is selected if FTMEN = 1 and DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.

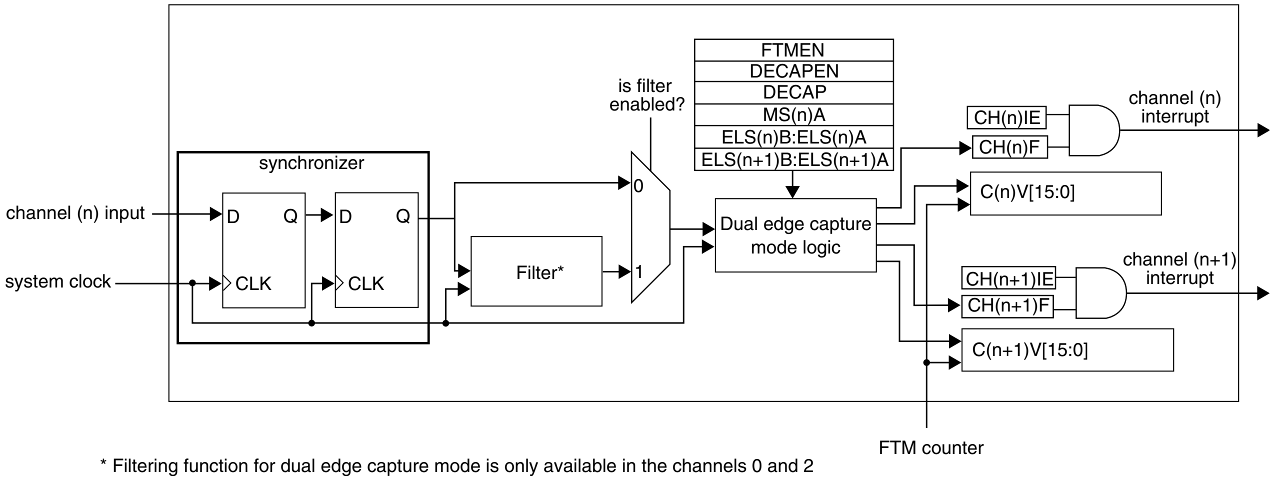


Figure 39-285. Dual Edge Capture mode block diagram

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n +1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the C(n)V and C(n +1)V registers are read. The only requirement is that C(n)V must be read before C(n +1)V.

Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.
- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in Free running counter.

39.4.24.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (FTMEN = 1), (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n +1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

39.4.24.2 Continuous Capture mode

The Continuous Capture mode is selected when (FTMEN = 1), (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

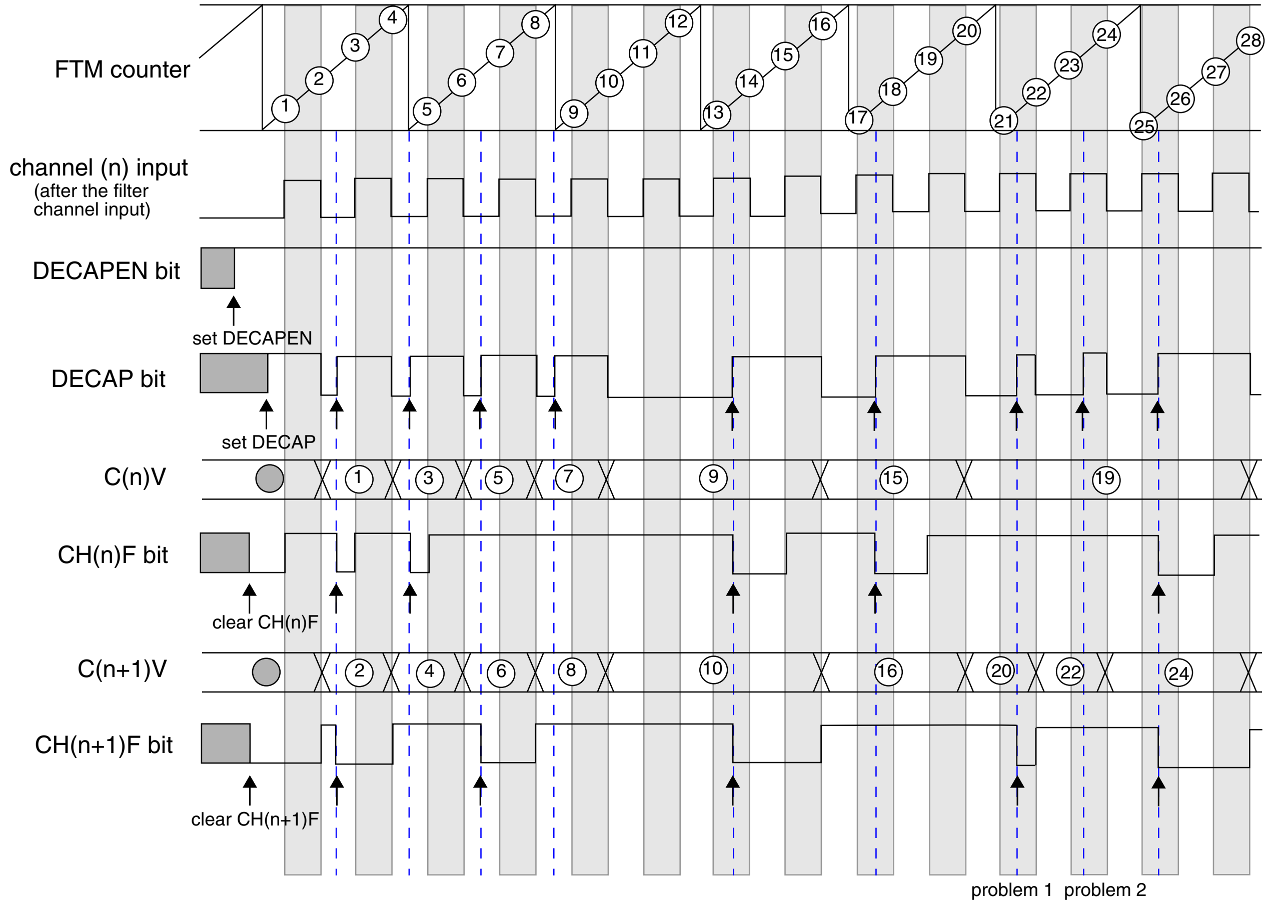
For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the CH(n)F and CH(n+1)F bits to start new measurements.

39.4.24.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1) and the channel (n+1) to capture falling edges (ELS(n+1)B:ELS(n+1)A = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0) and the channel (n+1) to capture rising edges (ELS(n+1)B:ELS(n+1)A = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in One-Shot Capture mode or Continuous Capture mode.

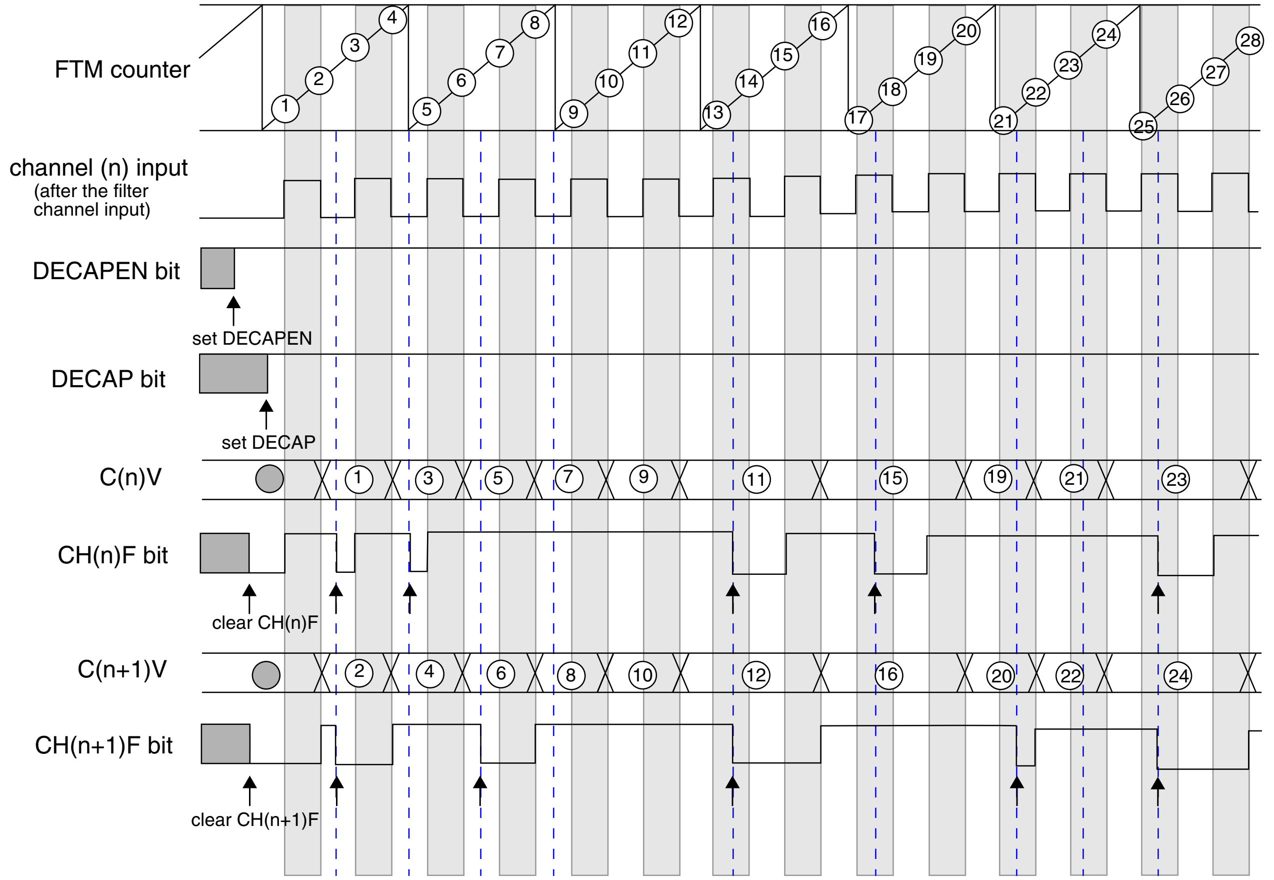
The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 39-286. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n +1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

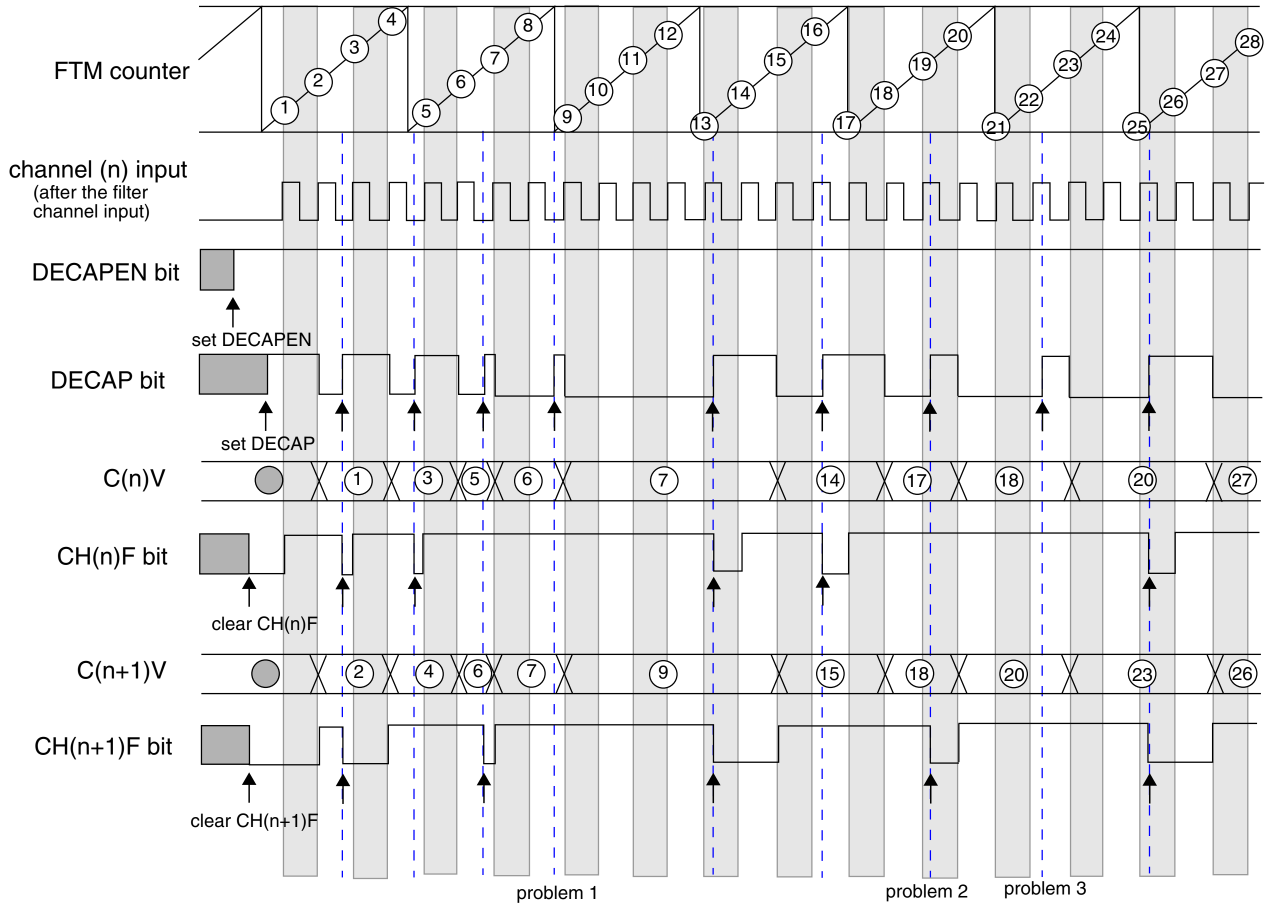
Figure 39-287. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement

39.4.24.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1 and ELS(n+1)B:ELS(n+1)A = 0:1), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0 and ELS(n+1)B:ELS(n+1)A = 1:0), then the period between two consecutive falling edges is measured.

The period measurement can be made in One-Shot Capture mode or Continuous Capture mode.

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

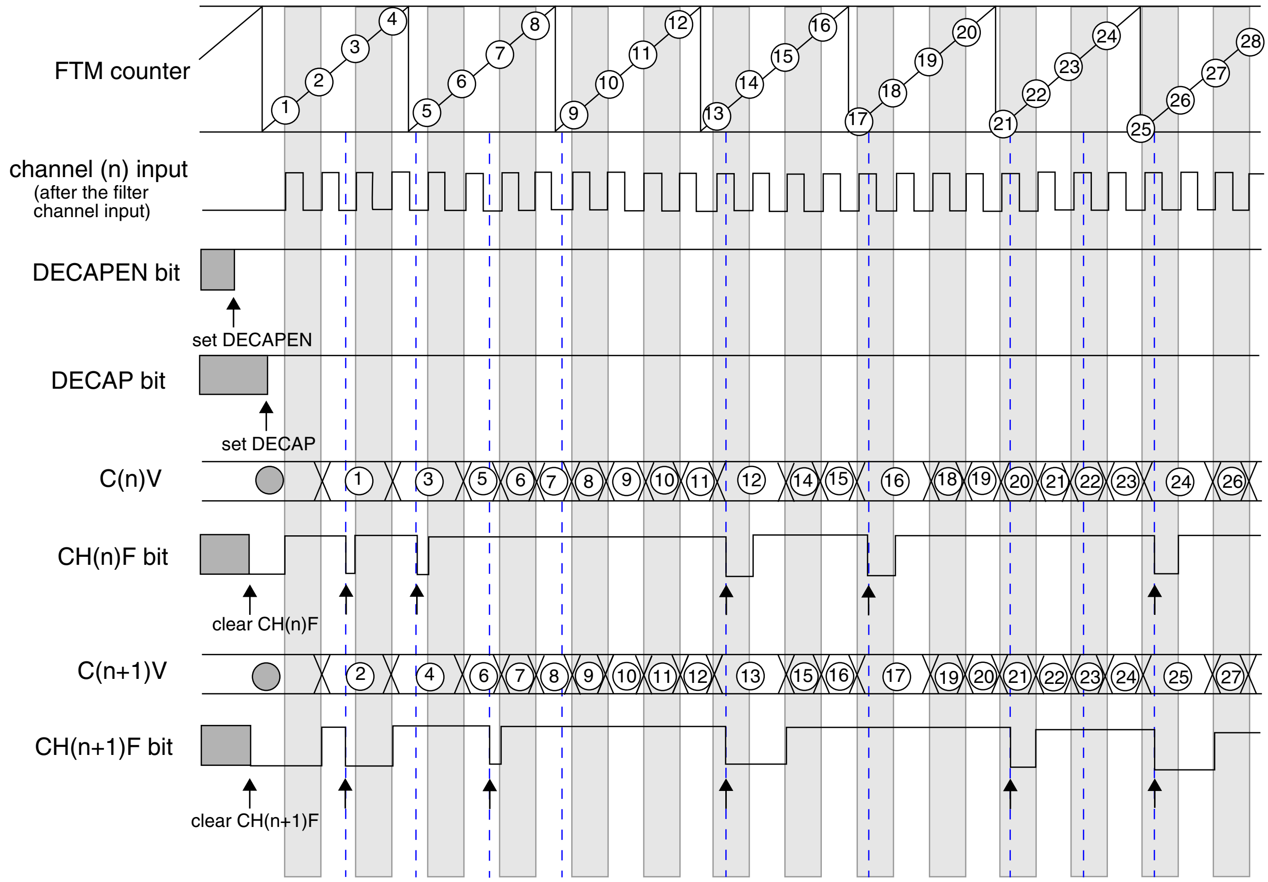


Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 39-288. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set

when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

Figure 39-289. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges

39.4.24.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal. C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

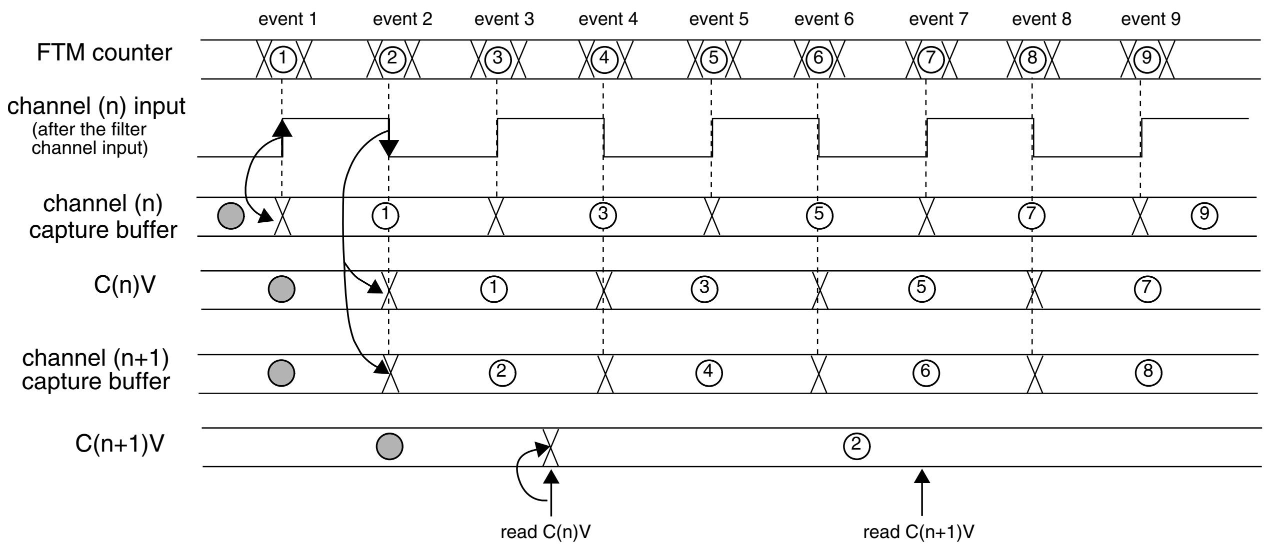


Figure 39-290. Dual Edge Capture mode read coherency mechanism

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

39.4.25 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (FTMEN = 1) and (QUADEN = 1). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

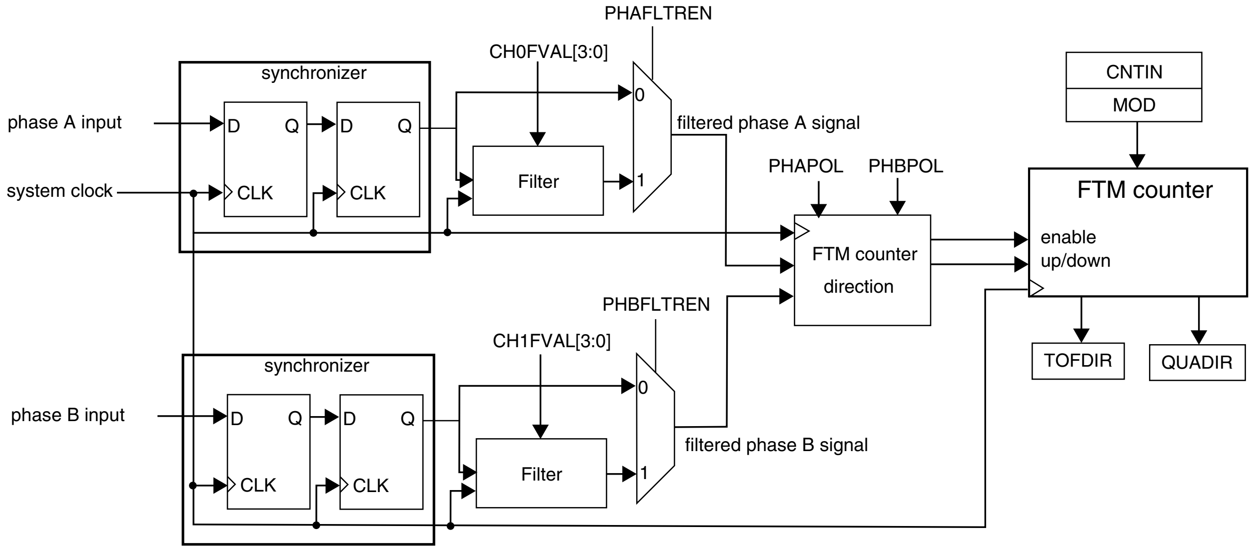

Figure 39-291. Quadrature Decoder block diagram

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; Filter for Input Capture mode. The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n +1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

Note

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

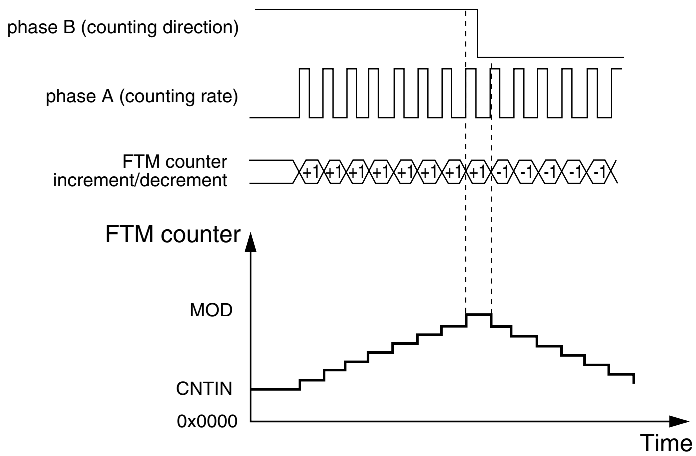

Figure 39-292. Quadrature Decoder – Count and Direction Encoding mode

If QUADMODE = 0, then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

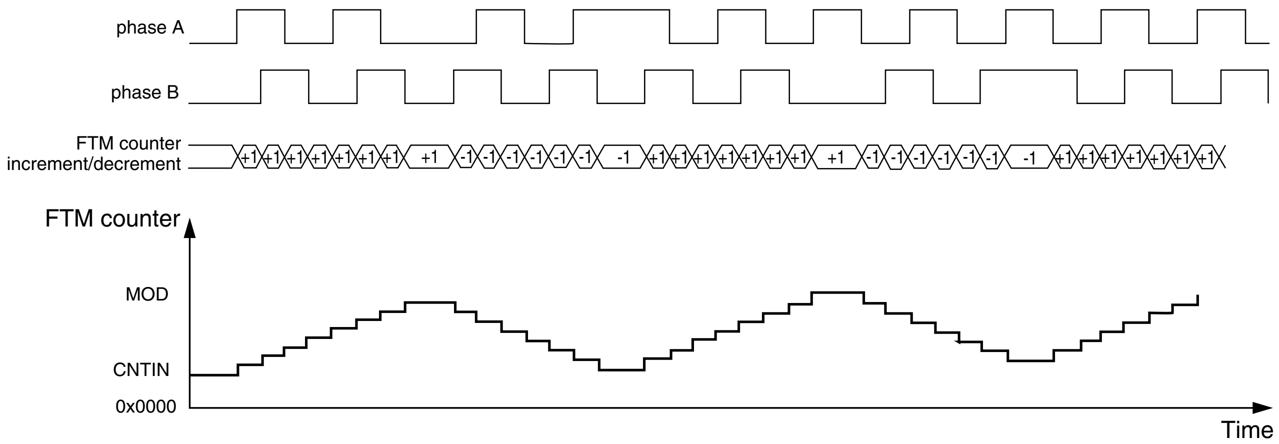

Figure 39-293. Quadrature Decoder – Phase A and Phase B Encoding mode

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

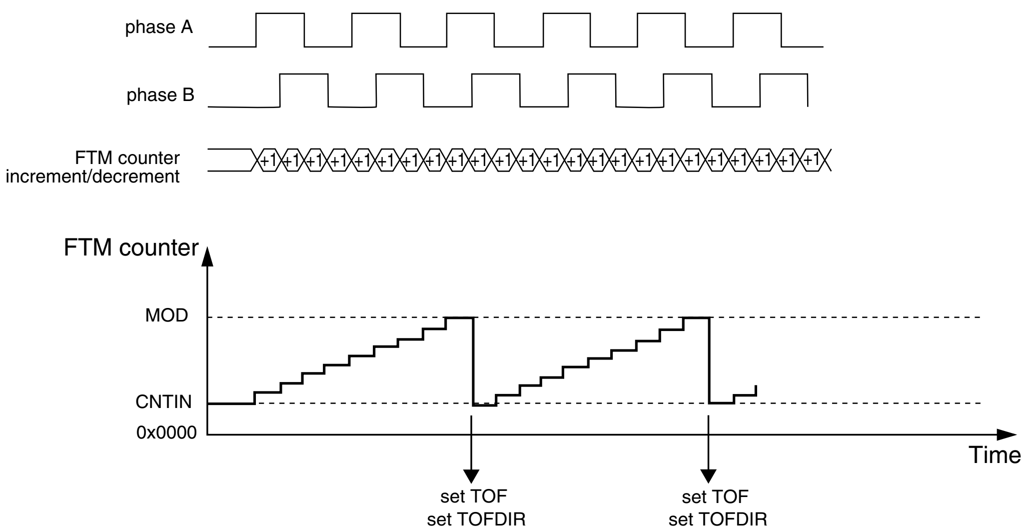

Figure 39-294. FTM Counter overflow in up counting for Quadrature Decoder mode

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

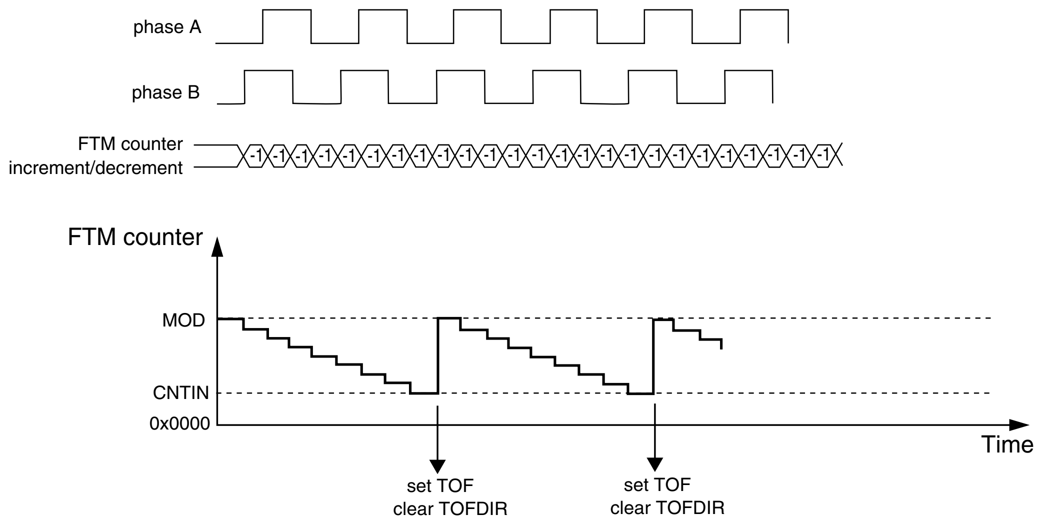

Figure 39-295. FTM counter overflow in down counting for Quadrature Decoder mode

39.4.25.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

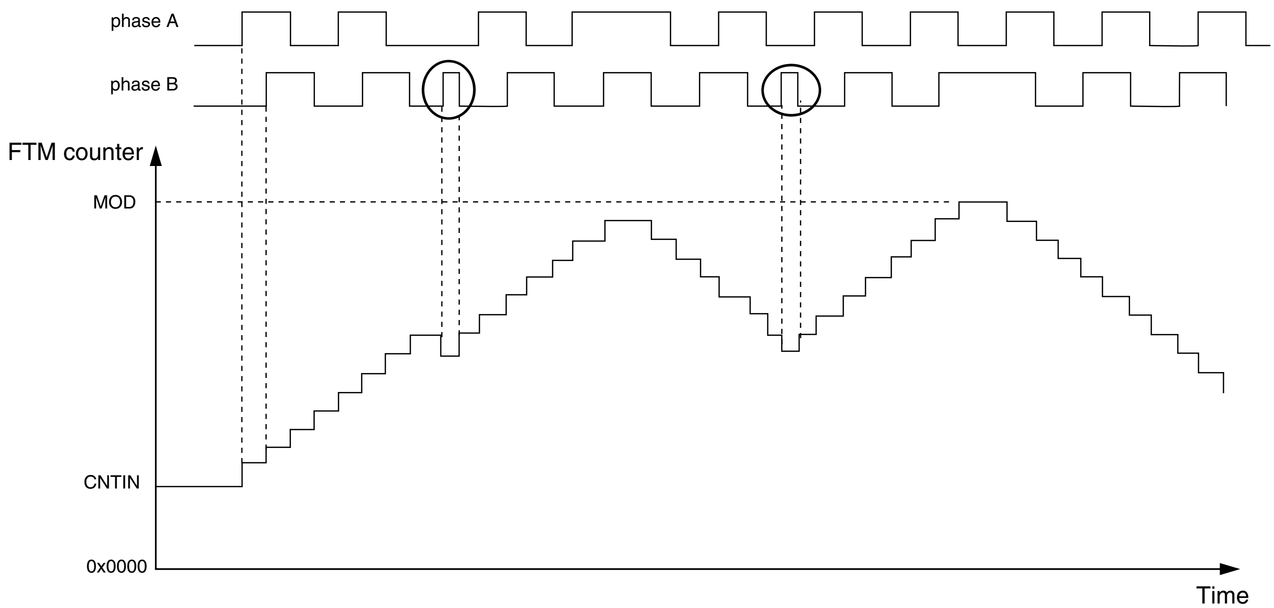

Figure 39-296. Motor position jittering in a mid count value

The following figure shows motor jittering produced by the phase B and A pulses respectively:

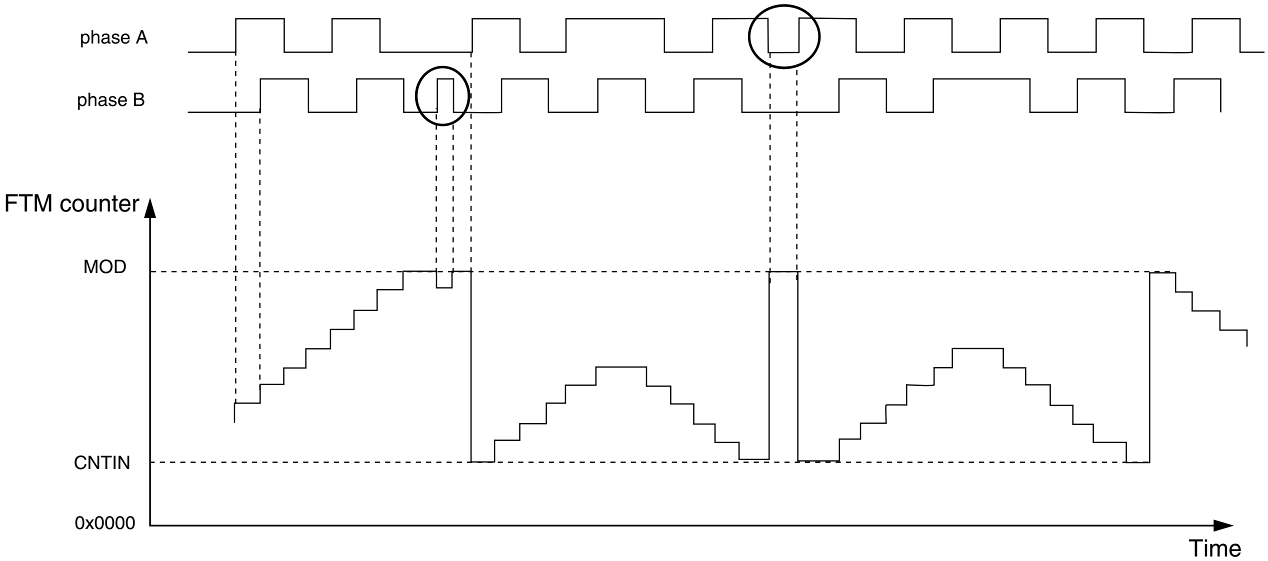

Figure 39-297. Motor position jittering near maximum and minimum count value

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

39.4.26 BDM mode

When the chip is in BDM mode, the BDMMODE[1:0] bits select the behavior of the FTM counter, the CH(n)F bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

Table 39-313. FTM behavior when the chip Is in BDM mode

BDMMODE	FTM Counter	CH(n)F Bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
00	Stopped	can be set	Functional mode	Writes to these registers bypass the registers buffers
01	Stopped	is not set	The channels outputs are forced to their safe value according to POLn bit	Writes to these registers bypass the registers buffers
10	Stopped	is not set	The channels outputs are frozen when the chip enters in BDM mode	Writes to these registers bypass the registers buffers

Table continues on the next page...

Table 39-313. FTM behavior when the chip Is in BDM mode (continued)

BDMMODE	FTM Counter	CH(n)F Bit	FTM Channels Output	Writes to MOD, CNTIN, and C(n)V Registers
11	Functional mode	can be set	Functional mode	Functional mode

Note that if BDMMODE[1:0] = 2'b00 then the channels outputs remain at the value when the chip enters in BDM mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this BDM mode.

- Write any value to CNT register; see Counter reset. In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see FTM counter synchronization. In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See Initialization.

Note

The BDMMODE[1:0] = 2'b00 must not be used with the Fault control. Even if the fault control is enabled and a fault condition exists, the channels outputs values are updated as above.

39.4.27 Intermediate load

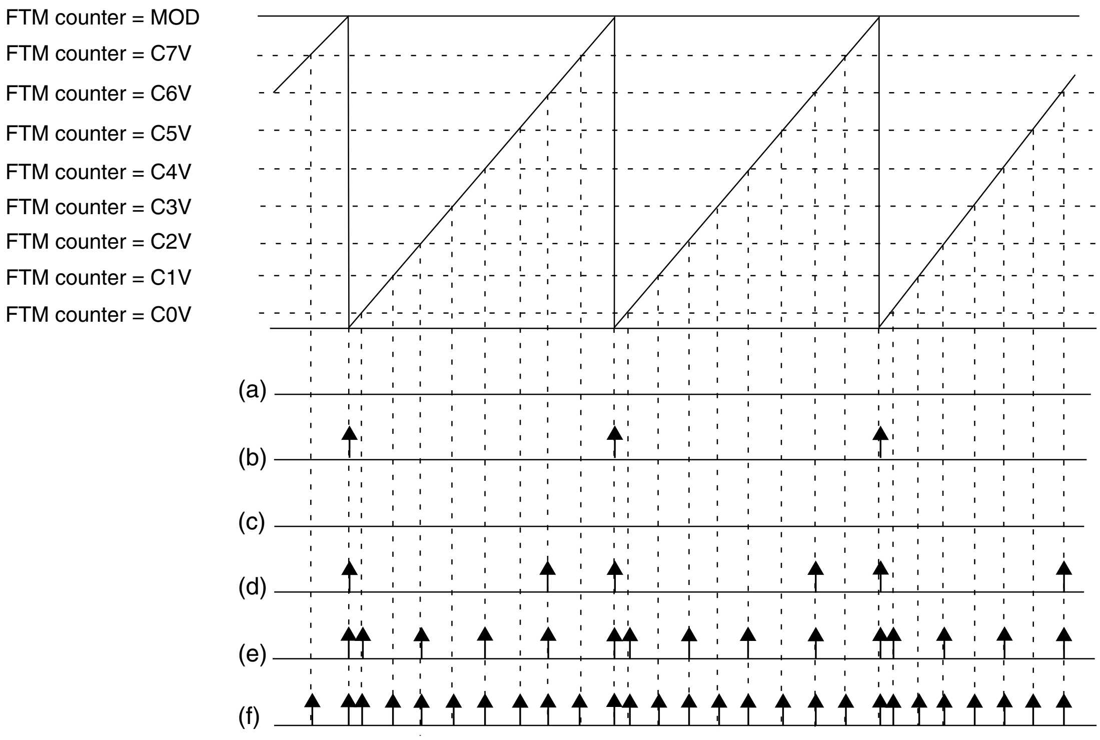
The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

Table 39-314. When possible loading points are enabled

Loading point	Enabled
When the FTM counter wraps from MOD value to CNTIN value	Always
At the channel (j) match (FTM counter = C(j)V)	When CHjSEL = 1

The following figure shows some examples of enabled loading points.



NOTE

(a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
(b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
(c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
(d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
(e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
(f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

Figure 39-298. Loading points for intermediate load

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

Table 39-315. Conditions for loads occurring at the next enabled loading point

When a new value was written	Then
To the MOD register	The MOD register is updated with its write buffer value.
To the CNTIN register and CNTINC = 1	The CNTIN register is updated with its write buffer value.
To the C(n)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n)V register is updated with its write buffer value.
To the C(n+1)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n+1)V register is updated with its write buffer value.

NOTE

- If ELSjB and ELSjA bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELSjB and ELSjA bits are zero, then the generated signal is not available on channel (j) output.
- If CHjIE = 1, then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.
- The intermediate load feature must be used only in Combine mode.

39.4.28 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

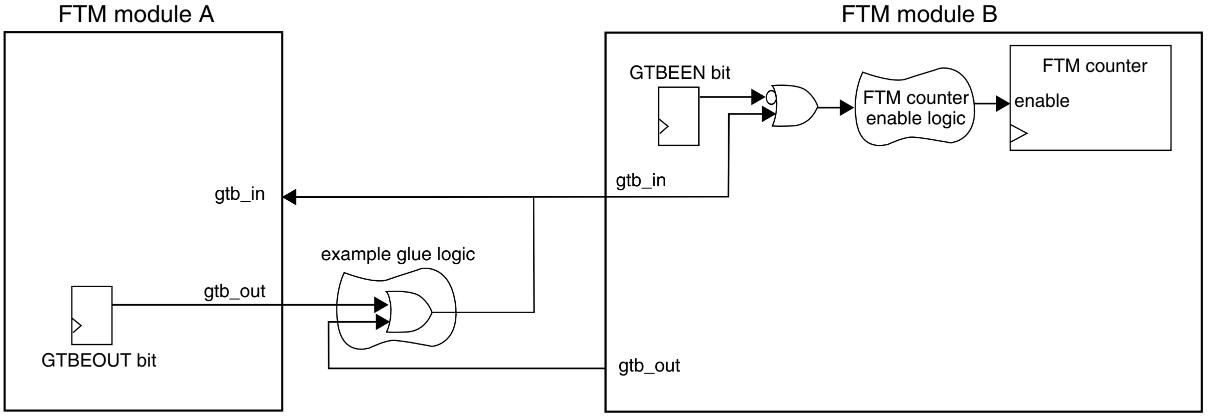


Figure 39-299. Global time base (GTB) block diagram

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb_in*, and the output signal *gtb_out*. The GTBEEN bit enables gtb_in to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when gtb_in is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the gtb_out signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the gtb_in and gtb_out signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip configuration details for the chip's specific implementation.

NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the gtb_in signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

39.4.28.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

39.5 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 00b);
- the timer overflow interrupt is zero, see Timer Overflow Interrupt;

- the channels interrupts are zero, see Channel (n) Interrupt;
- the fault interrupt is zero, see Fault Interrupt;
- the channels are in input capture mode, see Input Capture mode;
- the channels outputs are zero;
- the channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0:0) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configurated (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) (Counter reset).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).

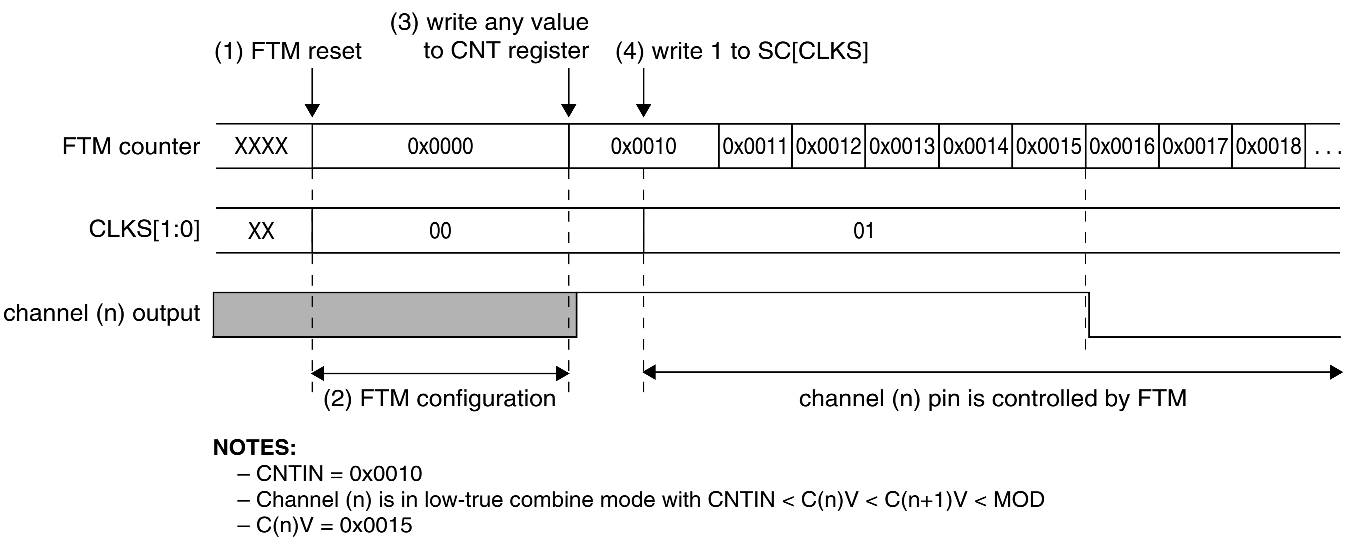

Figure 39-300. FTM behavior after reset when the channel (n) is in Combine mode

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT

register (item 3). In this case, use the software output control (Software output control) or the initialization (Initialization) to update the channel output to the selected value (item 4).

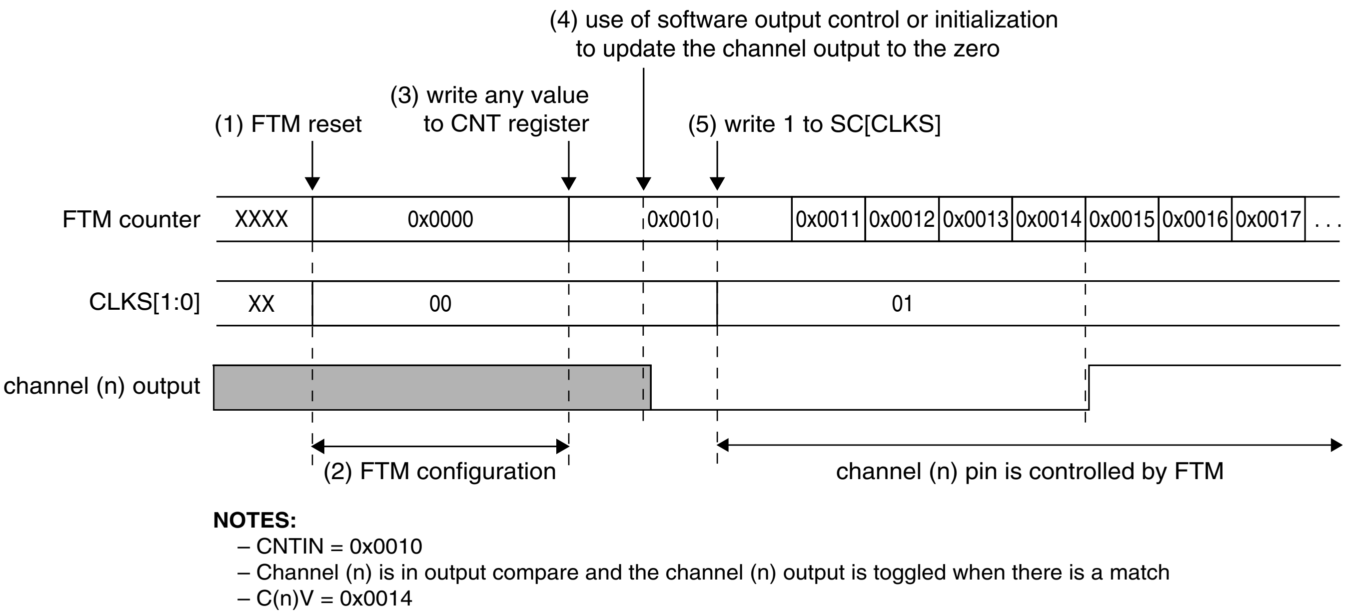

Figure 39-301. FTM behavior after reset when the channel (n) is in Output Compare mode

39.6 FTM Interrupts

39.6.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

39.6.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

39.6.3 Fault Interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

Chapter 40
Periodic Interrupt Timer (PIT)

40.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

40.1.1 Block diagram

The following figure shows the block diagram of the PIT module.

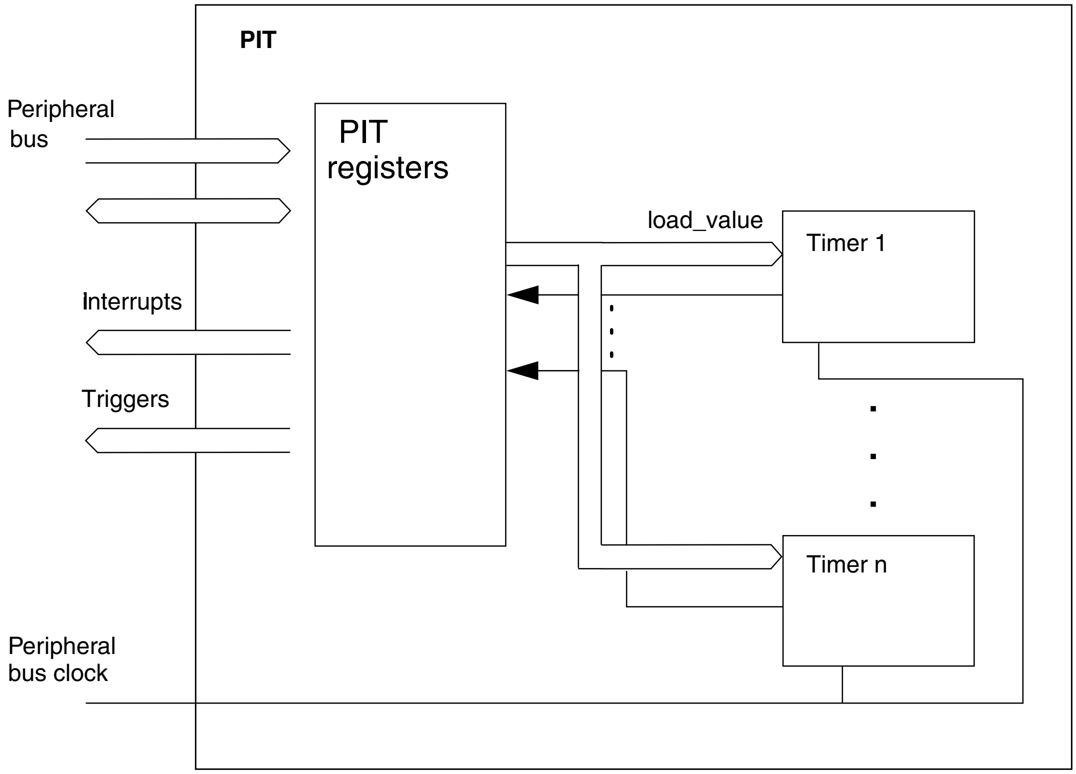

Figure 40-1. Block diagram of the PIT

NOTE

See the chip configuration details for the number of PIT channels used in this MCU.

40.1.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

40.2 Signal description

The PIT module has no external pins.

40.3 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip configuration details for the number of PIT channels used in this MCU.

PIT_MCR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved.
1 MDIS	Module Disable - (PIT section) Disables the standard timers. This field must be enabled before any other setup is done. 0 Clock for standard PIT timers is enabled. 1 Clock for standard PIT timers is disabled.
0 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0 Timers continue to run in Debug mode. 1 Timers are stopped in Debug mode.

40.3.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Address: 4003_7000h base + E0h offset = 4003_70E0h

Bit	31–0
R	LTH

Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

PIT_LTMR64H field descriptions

Field	Description
31–0 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

40.3.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Address: 4003_7000h base + E4h offset = 4003_70E4h

PIT_LDVAL*n* field descriptions

Field	Description
31–0 TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

40.3.5 Current Timer Value Register (PIT_CVAL*n*)

These registers indicate the current timer position.

Address: 4003_7000h base + 104h offset + (16d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PIT_TCTRL*n* field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CHN	Chain Mode When activated, Timer n-1 needs to expire before timer n can decrement by 1. Timer 0 cannot be chained.

Table continues on the next page...

PIT_TCTRLn field descriptions (continued)

Field	Description
	0 Timer is not chained. 1 Timer is chained to previous timer. For example, for Channel 2, if this field is set, Timer 2 is chained to Timer 1.
1 TIE	Timer Interrupt Enable When an interrupt is pending, or, TFLGn[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TFLGn[TIF] must be cleared first. 0 Interrupt requests from Timer n are disabled. 1 Interrupt will be requested whenever TIF is set.
0 TEN	Timer Enable Enables or disables the timer. 0 Timer n is disabled. 1 Timer n is enabled.

40.3.7 Timer Flag Register (PIT_TFLG*n*)

These registers hold the PIT interrupt flags.

Address: 4003_7000h base + 10Ch offset + (16d × i), where i=0d to 7d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PIT_TFLGn field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

40.4 Functional description

This section provides the functional description of the module.

40.4.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

40.4.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

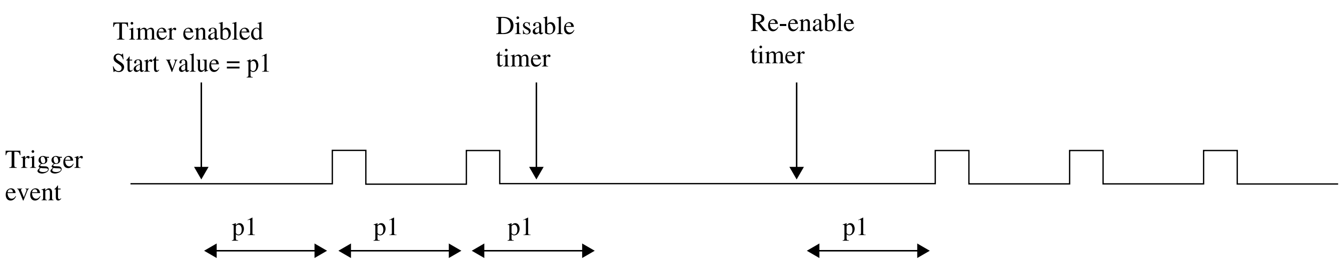

Figure 40-41. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

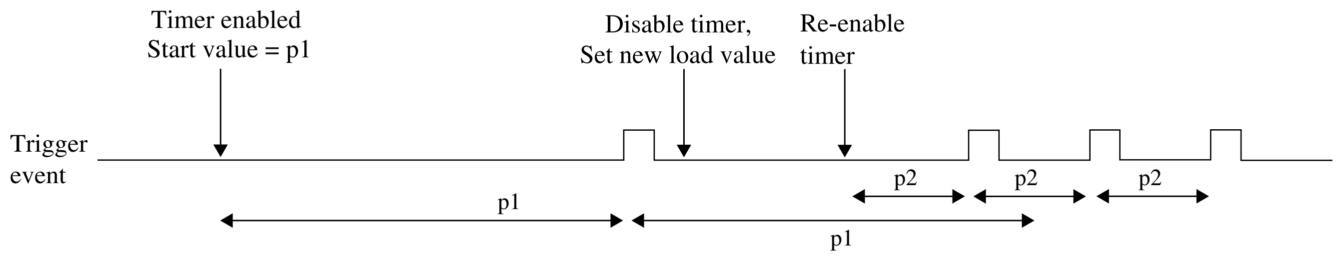

Figure 40-42. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

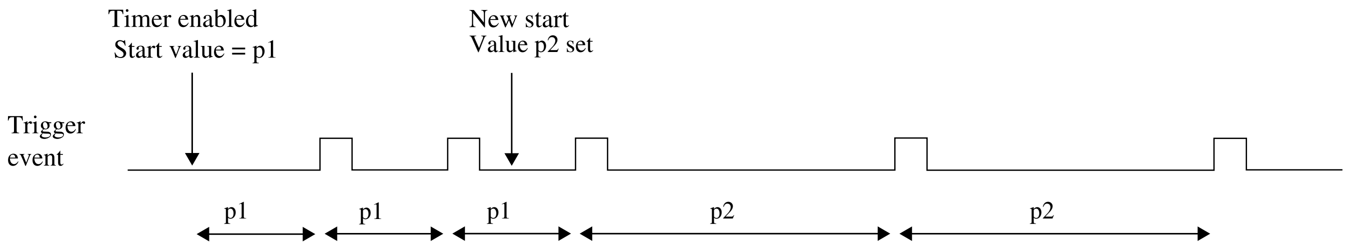

Figure 40-43. Dynamically setting a new load value

40.4.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

40.4.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

40.4.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

40.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

40.6 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 hour.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

40.7 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 41
Low-Power Timer (LPTMR)

41.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

41.1.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

41.1.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

Table 41-1. Modes of operation

Modes	Description
Run	The LPTMR operates normally.
Wait	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Stop	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Low-Leakage	The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request.
Debug	The LPTMR operates normally in Pulse Counter mode, but counter does not increment in Time Counter mode.

41.2 LPTMR signal descriptions

Table 41-2. LPTMR signal descriptions

LPTMRx_CSR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TCF	Timer Compare Flag TCF is set when the LPTMR is enabled and the CNR equals the CMR and increments. TCF is cleared when the LPTMR is disabled or a logic 1 is written to it. 0 The value of CNR is not equal to CMR and increments. 1 The value of CNR is equal to CMR and increments.
6 TIE	Timer Interrupt Enable When TIE is set, the LPTMR Interrupt is generated whenever TCF is also set. 0 Timer interrupt disabled. 1 Timer interrupt enabled.
5–4 TPS	Timer Pin Select Configures the input source to be used in Pulse Counter mode. TPS must be altered only when the LPTMR is disabled. The input connections vary by device. See the chip configuration details for information on the connections to these inputs. 00 Pulse counter input 0 is selected.

Table continues on the next page...

LPTMRx_CSR field descriptions (continued)

Field	Description
	01 Pulse counter input 1 is selected. 10 Pulse counter input 2 is selected. 11 Pulse counter input 3 is selected.
3 TPP	Timer Pin Polarity Configures the polarity of the input source in Pulse Counter mode. TPP must be changed only when the LPTMR is disabled. 0 Pulse Counter input source is active-high, and the CNR will increment on the rising-edge. 1 Pulse Counter input source is active-low, and the CNR will increment on the falling-edge.
2 TFC	Timer Free-Running Counter When clear, TFC configures the CNR to reset whenever TCF is set. When set, TFC configures the CNR to reset on overflow. TFC must be altered only when the LPTMR is disabled. 0 CNR is reset whenever TCF is set. 1 CNR is reset on overflow.
1 TMS	Timer Mode Select Configures the mode of the LPTMR. TMS must be altered only when the LPTMR is disabled. 0 Time Counter mode. 1 Pulse Counter mode.
0 TEN	Timer Enable When TEN is clear, it resets the LPTMR internal logic, including the CNR and TCF. When TEN is set, the LPTMR is enabled. While writing 1 to this field, CSR[5:1] must not be altered. 0 LPTMR is disabled and internal logic is reset. 1 LPTMR is enabled.

41.3.2 Low Power Timer Prescale Register (LPTMRx_PSR)

Address: 4004_0000h base + 4h offset = 4004_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LPTMRx_PSR field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–3 PRESCALE	Prescale Value Configures the size of the Prescaler in Time Counter mode or width of the glitch filter in Pulse Counter mode. PRESCALE must be altered only when the LPTMR is disabled. 0000 Prescaler divides the prescaler clock by 2; glitch filter does not support this configuration. 0001 Prescaler divides the prescaler clock by 4; glitch filter recognizes change on input pin after 2 rising clock edges. 0010 Prescaler divides the prescaler clock by 8; glitch filter recognizes change on input pin after 4 rising clock edges. 0011 Prescaler divides the prescaler clock by 16; glitch filter recognizes change on input pin after 8 rising clock edges. 0100 Prescaler divides the prescaler clock by 32; glitch filter recognizes change on input pin after 16 rising clock edges. 0101 Prescaler divides the prescaler clock by 64; glitch filter recognizes change on input pin after 32 rising clock edges. 0110 Prescaler divides the prescaler clock by 128; glitch filter recognizes change on input pin after 64 rising clock edges. 0111 Prescaler divides the prescaler clock by 256; glitch filter recognizes change on input pin after 128 rising clock edges. 1000 Prescaler divides the prescaler clock by 512; glitch filter recognizes change on input pin after 256 rising clock edges. 1001 Prescaler divides the prescaler clock by 1024; glitch filter recognizes change on input pin after 512 rising clock edges. 1010 Prescaler divides the prescaler clock by 2048; glitch filter recognizes change on input pin after 1024 rising clock edges. 1011 Prescaler divides the prescaler clock by 4096; glitch filter recognizes change on input pin after 2048 rising clock edges. 1100 Prescaler divides the prescaler clock by 8192; glitch filter recognizes change on input pin after 4096 rising clock edges. 1101 Prescaler divides the prescaler clock by 16,384; glitch filter recognizes change on input pin after 8192 rising clock edges. 1110 Prescaler divides the prescaler clock by 32,768; glitch filter recognizes change on input pin after 16,384 rising clock edges. 1111 Prescaler divides the prescaler clock by 65,536; glitch filter recognizes change on input pin after 32,768 rising clock edges.
2 PBYP	Prescaler Bypass When PBYP is set, the selected prescaler clock in Time Counter mode or selected input source in Pulse Counter mode directly clocks the CNR. When PBYP is clear, the CNR is clocked by the output of the prescaler/glitch filter. PBYP must be altered only when the LPTMR is disabled. 0 Prescaler/glitch filter is enabled. 1 Prescaler/glitch filter is bypassed.
1–0 PCS	Prescaler Clock Select Selects the clock to be used by the LPTMR prescaler/glitch filter. PCS must be altered only when the LPTMR is disabled. The clock connections vary by device. **NOTE:** See the chip configuration details for information on the connections to these inputs.

Table continues on the next page...

15–0 COUNTER	Counter Value

41.4 Functional description

41.4.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

41.4.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

NOTE

The clock source selected may need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency f_{LPTMR} defined in the device datasheet.

41.4.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

41.4.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every 2^2 to 2^{16} prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

41.4.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

41.4.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output will also deassert.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising-edges	The glitch filter output will also assert.

NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every 2^2 to 2^{16} prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

41.4.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

41.4.4 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

41.4.5 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

The CNR continues incrementing when the core is halted in Debug mode when configured for Pulse Counter mode, the CNR will stop incrementing when the core is halted in Debug mode when configured for Time Counter mode.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

41.4.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

When	Then
The CMR is set to 0 with CSR[TFC] clear	The LPTMR hardware trigger will assert on the first compare and does not deassert.
The CMR is set to a nonzero value, or, if CSR[TFC] is set	The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR.

41.4.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

Chapter 42
10/100-Mbps Ethernet MAC (ENET)

42.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The MAC-NET core, in conjunction with a 10/100 MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

42.2 Overview

The core implements a dual speed 10/100 Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100 Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

The programmable 10/100 Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

42.2.1 Features

The MAC-NET core includes the following features.

42.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero length Preamble
- Dynamically configurable to support 10/100 Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive

- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- MII internal loopback
- MDIO master interface for PHY device configuration and management with two programmable MDIO base addresses
- Supports legacy FEC buffer descriptors
- Important Note:The theoretical maximum performance of 1 Gbps ENET is limited to 470 Mbps (total for Tx and Rx) due to Chip internal bus throughput limitation. The actual measured performance in an optimized environment is up to 400 Mbps. See erratum ERR004512 in the device silicon errata document.

42.2.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked

- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

42.2.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames
- Allows reference clock to be chosen independently of network speed
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization
- Provides a 4-channel IEEE 1588 timer — each channel supports input capture and output compare using the 1588 counter

42.2.2 Block diagram

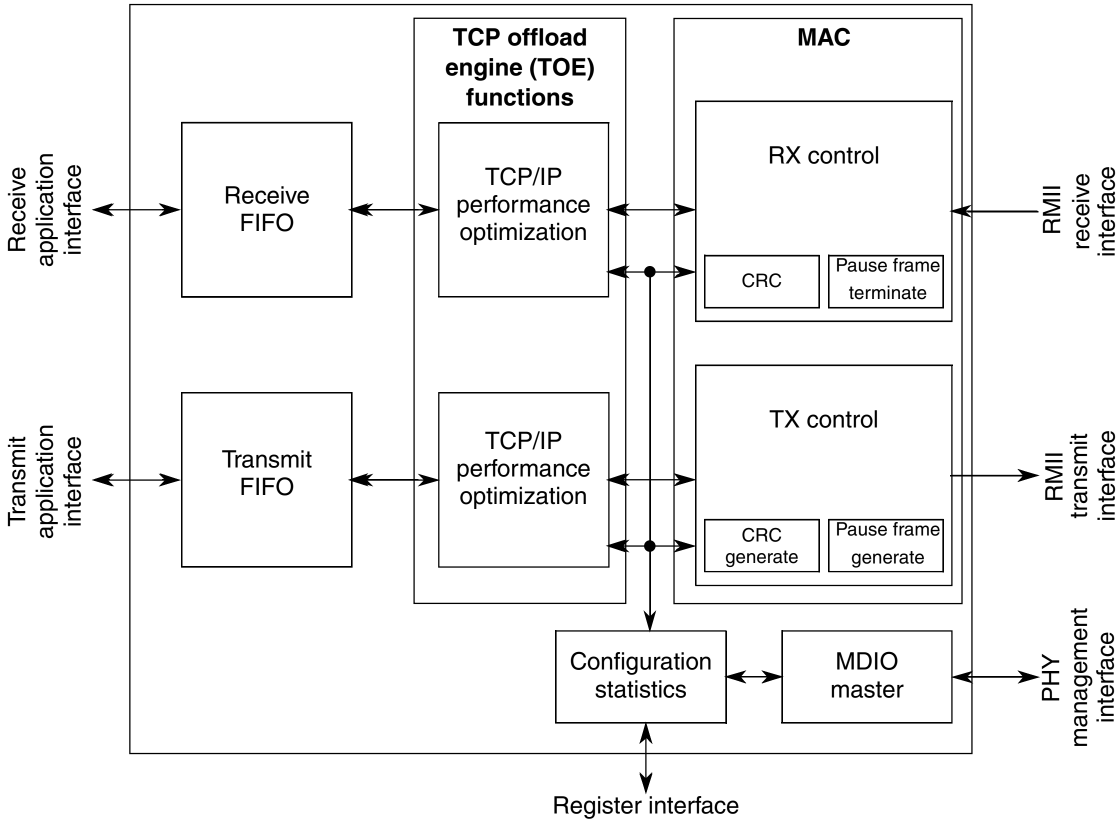

Figure 42-1. 10/100 Ethernet MAC-NET Core Block Diagram

42.3 External signal description

RMII	Description	I/O
—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.	I
—	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the RMII_CRS_DV pin.	I
RMII_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	O
RMII_MDIO	Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.	I/O

Table continues on the next page...

RMII	Description	I/O
—	In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.	I
RMII_CRS_DV	Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.	I
RMII_RXD[1:0]	Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.	I
RMII_RXER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	I
—	Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.	I
RMII_TXD[1:0]	Serial output Ethernet data. Only valid during TXEN assertion.	O
RMII_TXEN	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.	O
—	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	O
RMII_REF_CLK	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	I
—	In RGMII mode, this signal provide 125Mhz external reference clock input.	I
1588_TMR*n*	Capture/compare block input/output event bus. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR*n* register for inspection by software. When configured for compare, the corresponding signal 1588_TMR*n* is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCR*n*. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSR*n*[TIE] or ENET_TCSR*n*[TDRE] is set.	I/O

Table continues on the next page...

RMII	Description	I/O
ENET_1588_CLKIN	Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds	I

42.4 Memory map/register definition

Reserved bits should be written with 0 and ignored on read to allow future extension. Unused registers read zero and a write has no effect.

The table found here summarizes the Ethernet registers.

Table 42-1. Register map summary

Offset Address	Section	Description
0x000	Configuration	Core control and status registers
0x200	Statistics counters	MIB block counters. See Statistic event counters.
0x400	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x600	Capture/compare block	Registers for the capture/compare block

42.4.1 Interrupt Event Register (ENETx_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: Base address + 4h offset

ENETx_EIR field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. **NOTE:** The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
27 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
26 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
25 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.

Table continues on the next page...

ENETx_EIR field descriptions (continued)

Field	Description
24 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
23 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
21 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
19 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
18 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
17 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
16 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
15 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
14–13 Reserved	This field is reserved.
12 Reserved	This field is reserved.
11–0 Reserved	This field is reserved.

42.4.2 Interrupt Mask Register (ENETx_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

ENETx_EIMR field descriptions (continued)

Field	Description
	corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
27 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
26 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
25 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
24 RXB	RXB Interrupt Mask Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
23 MII	MII Interrupt Mask Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
22 EBERR	EBERR Interrupt Mask Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
21 LC	LC Interrupt Mask Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

ENETx_EIMR field descriptions (continued)

Field	Description
20 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 Reserved	This field is reserved.

42.4.3 Receive Descriptor Active Register (ENETx_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_RDAR field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
23–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.4 Transmit Descriptor Active Register (ENETx_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: Base address + 14h offset

W								DBSWP	Reserved	DBGEN		EN1588	SLEEP	MAGICEN	ETHEREN	RESET
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_ECR field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 DBSWP	Descriptor Byte Swapping Enable Swaps the byte locations of the buffer descriptors. **NOTE:** This field must be written to 1 after reset. 0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
7 Reserved	This field is reserved. This field must be set to zero.
6 DBGEN	Debug Enable Enables the MAC to enter hardware freeze mode when the device enters debug mode. 0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
3 SLEEP	Sleep Mode Enable 0 Normal operating mode. 1 Sleep mode.
2 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection. **NOTE:** MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. 0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.
1 ETHEREN	Ethernet Enable Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions:

Table continues on the next page...

ENETx_ECR field descriptions (continued)

Field	Description
	• RESET is set by software • An error condition causes the EBERR field to set. **NOTE:** ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only *after* all other ENET-related registers have been configured. 0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. 1 MAC is enabled, and reception and transmission are possible.
0 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

42.4.6 MII Management Frame Register (ENETx_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENETx_MMFR field descriptions

Field	Description
31–30 ST	Start Of Frame Delimiter These fields must be programmed to 01 for a valid MII management frame.
29–28 OP	Operation Code Determines the frame operation. 00 Write frame operation, but not MII compliant. 01 Write frame operation for a valid MII management frame. 10 Read frame operation for a valid MII management frame. 11 Read frame operation, but not MII compliant.

Table continues on the next page...

ENETx_MMFR field descriptions (continued)

Field	Description
27–23 PA	PHY Address Specifies one of up to 32 attached PHY devices.
22–18 RA	Register Address Specifies one of up to 32 registers within the specified PHY device.
17–16 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
15–0 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

42.4.7 MII Speed Control Register (ENETx_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

If the internal module clock is 25 MHz, programming this register to 0x0000_0004 results in an MDC as stated in the following equation:

25 MHz / ((4 + 1) x 2) = 2.5 MHz

The following table shows the optimum values for MII_SPEED as a function of internal module clock frequency.

Table 42-62. Programming Examples for MSCR

Internal MAC clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Address: Base address + 44h offset

ENETx_MSCR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 HOLDTIME	Holdtime On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the holdtime on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
7 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
6–1 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: 1/((MII_SPEED + 1) x 2) of the internal module clock frequency
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.8 MIB Control Register (ENETx_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

Address: Base address + 64h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ENETx_RCR field descriptions

Field	Description
31 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.

Table continues on the next page...

ENETx_RCR field descriptions (continued)

Field	Description
30 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLC] field.
29–16 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
15 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
14 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. **NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
13 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
12 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
11–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 RMII_10T	Enables 10-Mbps mode of the RMII . 0 100 Mbps operation. 1 10 Mbps operation.
8 RMII_MODE	RMII Mode Enable Specifies whether the MAC is configured for MII mode or RMII operation .

Table continues on the next page...

ENETx_RCR field descriptions (continued)

Field	Description
	0 MAC configured for MII mode. 1 MAC configured for RMII operation.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 FCE	Flow Control Enable If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
4 BC_REJ	Broadcast Frame Reject If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
3 PROM	Promiscuous Mode All frames are accepted regardless of address matching. 0 Disabled. 1 Enabled.
2 MII_MODE	Media Independent Interface Mode This field must always be set. 0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.
1 DRT	Disable Receive On Transmit 0 Receive path operates independently of transmit. Used for full-duplex or to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. Normally used for half-duplex mode.
0 LOOP	Internal Loopback This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0. 0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.

42.4.10 Transmit Control Register (ENETx_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: Base address + C4h offset

ENETx_TCR field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 CRCFWD	Forward Frame From Application With CRC 0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.
8 ADDINS	Set MAC Address On Transmit

Table continues on the next page...

ENETx_TCR field descriptions (continued)

Field	Description
	0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
7–5 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
4 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
3 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
2 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

42.4.11 Physical Address Lower Register (ENETx_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames. This register is not reset and you must initialize it.

Address: Base address + E4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_PALR field descriptions

Field	Description
31–0 PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

42.4.12 Physical Address Upper Register (ENETx_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames. The upper 16 bits of this register are not reset and you must initialize it.

Address: Base address + E8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENETx_PAUR field descriptions

Field	Description
31–16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
15–0 TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

42.4.13 Opcode/Pause Duration Register (ENETx_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: Base address + ECh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENETx_GALR field descriptions

Field	Description
31–0 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

42.4.18 Transmit FIFO Watermark Register (ENETx_TFWR)

If TFR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement. For example, worst case bus access latency by the transmit data DMA channel.

Address: Base address + 144h offset

ENETx_TFWR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 STRFWD	Store And Forward Enable 0 Disabled, the transmission start threshold is programmed in TFWR. 1 Enabled.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 TFWR	Transmit FIFO Write If STRFWD is cleared, this field indicates the number of bytes written to the transmit FIFO before transmission of a frame begins. **NOTE:** If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. This chip may not support the maximum number of bytes written shown below. See the chip-specific information for the ENET module for this value. 000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. ... ... 111110 3968 bytes written. 111111 4032 bytes written.

42.4.19 Receive Descriptor Ring Start Register (ENETx_RDSR)

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

NOTE

This register must be initialized prior to operation

Address: Base address + 180h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENETx_TDSR field descriptions

Field	Description
31–3 X_DES_START	Pointer to the beginning of the transmit buffer descriptor queue.
2–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.21 Maximum Receive Buffer Size Register (ENETx_MRBR)

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, bits 3–0 are set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: Base address + 188h offset

Bit	31–14	13–4	3–0
R	0	R_BUF_SIZE	0

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–0 TRUNC_FL	Frame Truncation Length

Table continues on the next page...

ENETx_FTRL field descriptions (continued)

Field	Description
	Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL]. **NOTE:** Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

42.4.31 Transmit Accelerator Function Configuration (ENETx_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: Base address + 1C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ENETx_TACC field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
3 IPCHK	Enables insertion of IP header checksum. 0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
2–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENETx_TACC field descriptions (continued)

Field	Description
0 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

42.4.32 Receive Accelerator Function Configuration (ENETx_RACC)

Address: Base address + 1C4h offset

ENETx_RACC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. **NOTE:** This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
6 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENETx_RACC field descriptions (continued)

Field	Description
2 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
1 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
0 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

42.4.33 Timer Control Register (ENETx_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required. The fields are automatically cleared after the command completes.

Address: Base address + 400h offset

ENETx_ATCR field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENETx_ATCR field descriptions (continued)

Field	Description
13 SLAVE	Enable Timer Slave Mode 0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 CAPTURE	Capture Timer Value 0 No effect. 1 The current time is captured and can be read from the ATVR register.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PINPER	Enables event signal output assertion on period event. **NOTE:** Not all devices contain the event signal output. See the chip configuration details. 0 Disable. 1 Enable.
6–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PEREN	Enable Periodical Event 0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. **NOTE:** Not all devices contain the event signal output. See the chip configuration details.
3 OFFRST	Reset Timer On Offset Event 0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
2 OFFEN	Enable One-Shot Offset Event 0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENETx_ATCR field descriptions (continued)

Field	Description
0 EN	Enable Timer 0 The timer stops at the current value. 1 The timer starts incrementing.

42.4.34 Timer Value Register (ENETx_ATVR)

Address: Base address + 404h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENETx_ATPER field descriptions

Field	Description
31–0 PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^{9}) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.

42.4.37 Timer Correction Register (ENETx_ATCOR)

Address: Base address + 410h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ENETx_TCCR*n* field descriptions

Field	Description
31–0 TCC	Timer Capture Compare This register is double buffered between the module clock and 1588 clock domains.

ENETx_TCCRn field descriptions (continued)

Field	Description
	When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag. The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for Capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.

42.4.127 Statistic event counters

The following table shows the locations of the statistic event counters in the module's memory map. Definitions of these registers can be found in IETF RFC 2819, *Remote Network Monitoring Management Information Base*.

NOTE

All counters are 32 bits wide with the top 16 bits reserved/ignored, except for the following:

- RMON_T_OCTETS
- IEEE_T_OCTETS_OK
- RMON_R_OCTETS
- IEEE_R_OCTETS_OK

Table 42-158. Statistic event counters memory map

Address offset from ENET base address	Register

0x2C4	RMON Rx Octets (RMON_R_OCTETS)
0x2C8	Count of frames not counted correctly (IEEE_R_DROP). **NOTE:** Counter increments if a frame with invalid/missing SFD character is detected and has been dropped. None of the other counters increments if this counter increments.
0x2CC	Frames Received OK (IEEE_R_FRAME_OK)
0x2D0	Frames Received with CRC Error (IEEE_R_CRC)
0x2D4	Frames Received with Alignment Error (IEEE_R_ALIGN)
0x2D7	Receive FIFO Overflow count (IEEE_R_MACERR)
0x2DC	Flow Control Pause frames received (IEEE_R_FDXFC)
0x2E0	Octet count for Frames Rcvd w/o Error (IEEE_R_OCTETS_OK). Counts total octets (includes header and FCS fields)

42.5 Functional description

This section provides a complete functional description of the MAC-NET core.

42.5.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

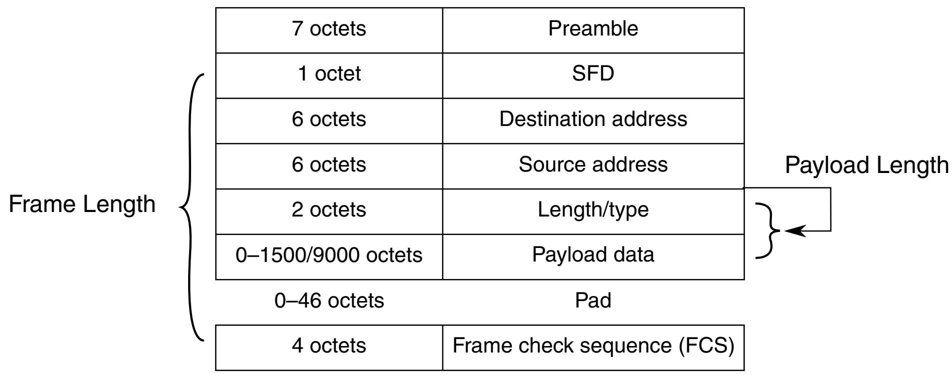

Figure 42-152. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

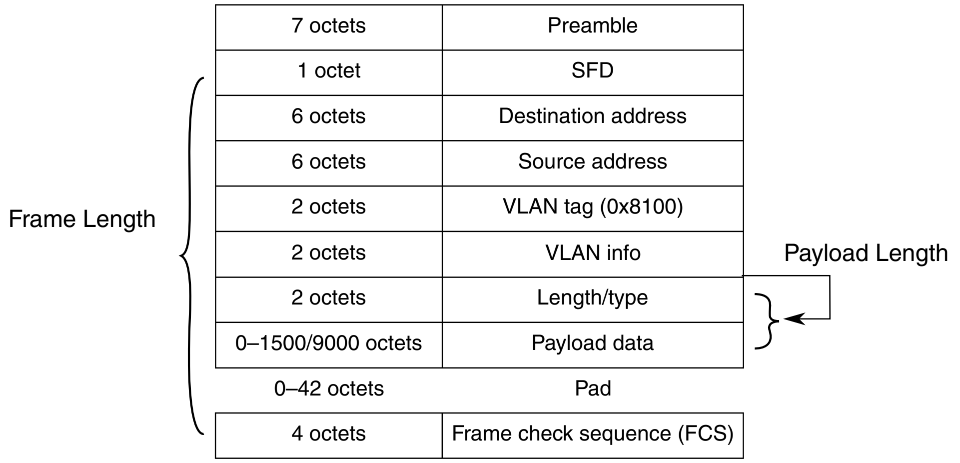

Figure 42-153. VLAN-tagged MAC frame format overview

Table 42-159. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. • If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

42.5.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 42-160. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01

26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

42.5.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

42.5.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

42.5.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 42-161. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

42.5.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 42-162. IPv4 header format

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="4">Version</td><td colspan="4">IHL</td><td colspan="8">TOS</td><td colspan="16">Length</td></tr>
<tr><td colspan="16">Fragment ID</td><td colspan="3">Flags</td><td colspan="13">Fragment offset</td></tr>
<tr><td colspan="8">TTL</td><td colspan="8">Protocol</td><td colspan="16">Header checksum</td></tr>
<tr><td colspan="32">Source address</td></tr>
<tr><td colspan="32">Destination address</td></tr>
<tr><td colspan="32">Options</td></tr>
</table>

Table 42-163. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

42.5.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly.The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/ traffic class fields).

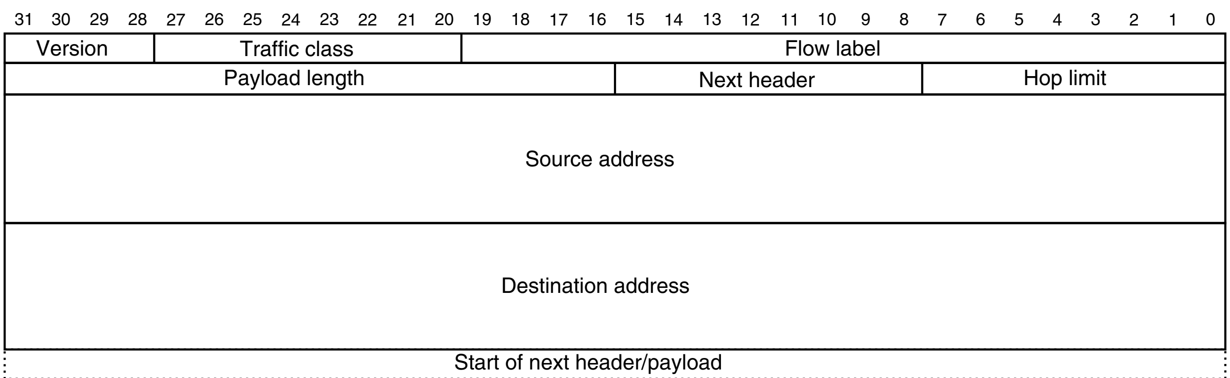

Figure 42-154. IPv6 header format

Table 42-164. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

42.5.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 42-165. ICMP header format

<table>
<tr><td>31</td><td>30 29 28</td><td>27 26 25 24</td><td>23 22 21 20</td><td>19 18 17 16</td><td>15 14 13 12</td><td>11 10 9 8</td><td>7 6 5 4</td><td>3 2 1 0</td></tr>
<tr><td colspan="3">Type</td><td colspan="2">Code</td><td colspan="4">Checksum</td></tr>
<tr><td colspan="9">ICMP message data</td></tr>
</table>

Table 42-166. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

42.5.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 42-167. UDP header format

31	30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port					Destination port			
Length					Checksum			

Table 42-168. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

42.5.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 42-169. TCP header format

31	30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port					Destination port			
Sequence number								
Acknowledgement number								
Offset				Flags	Window			
Checksum					Urgent pointer			
Options								

Table 42-170. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5

Table continues on the next page...

Table 42-170. TCP header fields (continued)

Field name	Description
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

42.5.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

42.5.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

42.5.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 42-171 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 42-171. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 42-172. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

42.5.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 42-173. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

42.5.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

42.5.3.2.1 PTPv1 header

Table 42-174. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							

Table continues on the next page...

Table 42-174. Common PTPv1 message header (continued)

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in Table 42-175 :

Table 42-175. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

42.5.3.2.2 PTPv2 header

Table 42-176. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 42-177. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 42-178. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

42.5.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing

- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

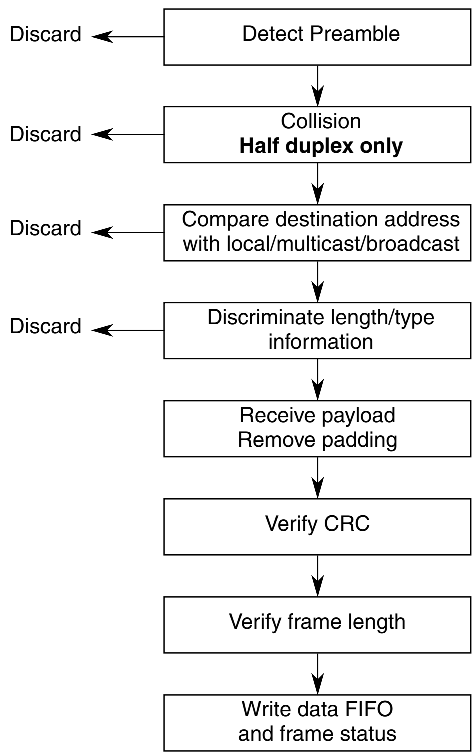

Figure 42-155. MAC receive flow

42.5.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

42.5.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100 Mbps operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

42.5.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

42.5.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

42.5.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32}+ x^{26}+ x^{23}+ x^{22}+ x^{16}+ x^{12}+ x^{11}+ x^{10}+ x^{8}+ x^{7}+ x^{5}+ x^{4}+ x^{2}+ x^{1}+ 1$

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

42.5.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 42-179. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

42.5.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

42.5.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

42.5.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

42.5.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

42.5.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

42.5.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: $x^{31}, x^{30}, \ldots, x^{1}, x^{0}$.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

42.5.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

42.5.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

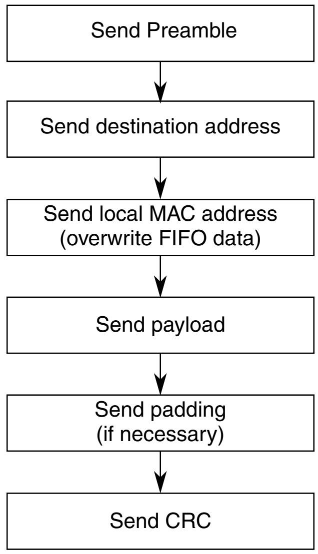

Figure 42-156. Frame transmit overview

42.5.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

42.5.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

42.5.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

42.5.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 27 byte-times (64 and 216 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

42.5.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

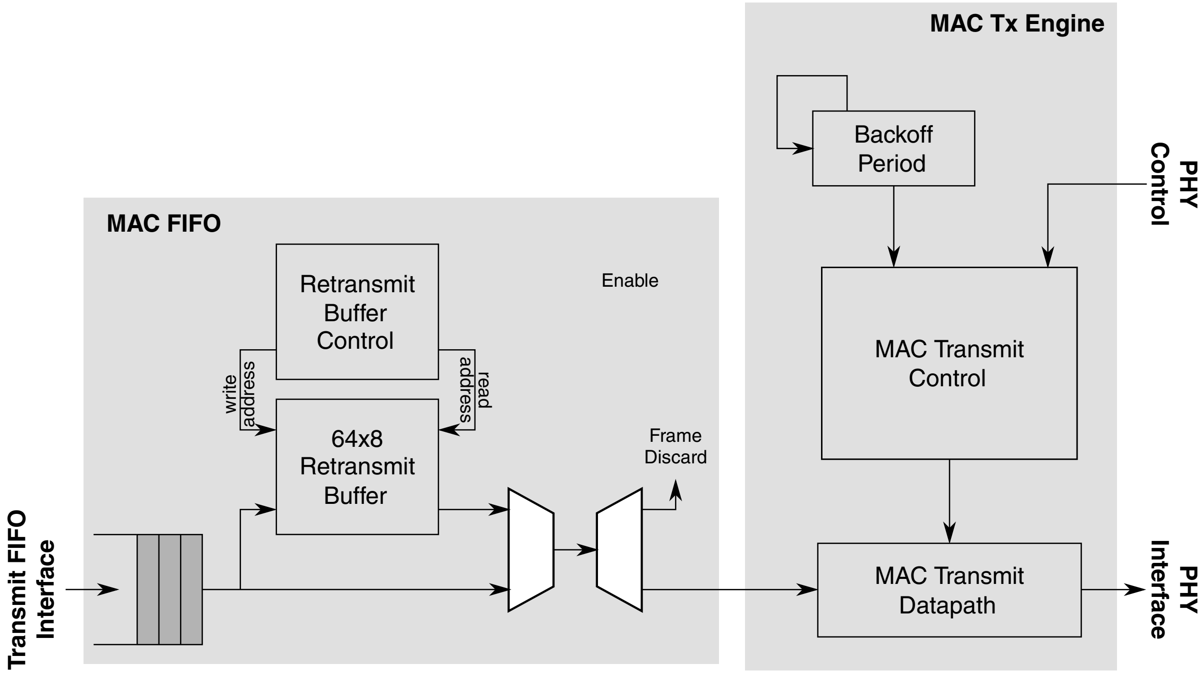

Figure 42-157. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- k = min(*n*, N); where *n* is the number of retransmissions and N = 10

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

42.5.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

42.5.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

42.5.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

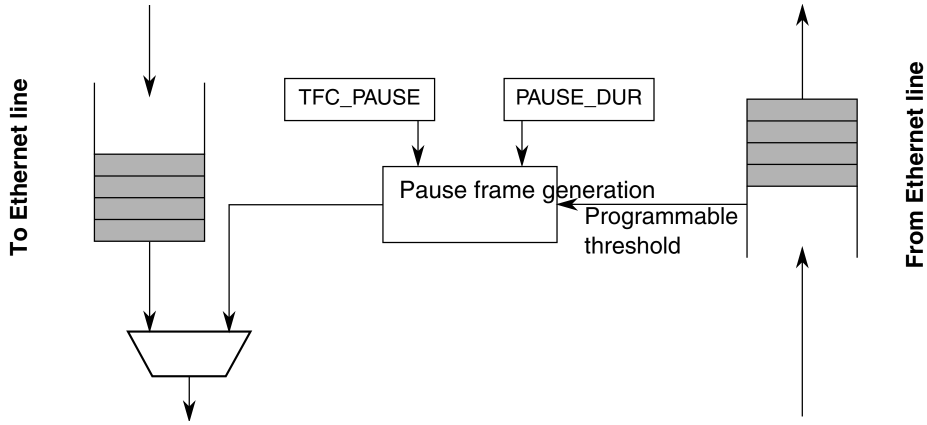

Figure 42-158. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

42.5.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

42.5.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET*n*_ECR[SLEEP]. At the same time ENET*n*_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the ENET*n*_ECR register bits.

When the core is in Sleep mode:

- The MAC transmit logic is disabled.
- The core FIFO receive/transmit functions are disabled.
- The MAC receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

42.5.7.2 Magic packet detection

The core is designed to detect magic packets (see Magic packets) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

42.5.7.3 Wakeup

When a magic packet is detected, indicated by ENET*n*_EIR[WAKEUP], ENET*n*_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET*n*_ECR[MAGICEN], disabling magic packet detection.

42.5.8 IP accelerator functions

The following sections describe the IP accelerator functions.

42.5.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 42-180. IPv4 pseudo-header for checksum calculation

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="32">Source address</td></tr>
<tr><td colspan="32">Destination address</td></tr>
<tr><td colspan="8">Zero</td><td colspan="8">Protocol</td><td colspan="16">TCP/UDP length</td></tr>
</table>

Table 42-181. IPv6 pseudo-header for checksum calculation

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="32">Source address</td></tr>
<tr><td colspan="32">Destination address</td></tr>
<tr><td colspan="32">TCP/UDP length</td></tr>
<tr><td colspan="24">Zero</td><td colspan="8">Next header</td></tr>
</table>

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

42.5.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

42.5.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 42-182.

Table 42-182. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

42.5.8.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

> SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

42.5.8.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

42.5.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

42.5.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

42.5.8.6 IPv6 support

The following sections describe the IPv6 support.

42.5.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

42.5.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

42.5.9 Resets and stop controls

The following sections describe the resets and stop controls.

42.5.9.1 Hardware reset

To reset the Ethernet module, set ENET*n*_ECR[RESET].

42.5.9.2 Soft reset

When ENET*n*_ECR[ETHER_EN] is cleared during operation, the following occurs:

- DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.

- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

42.5.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the RMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

42.5.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

42.5.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET*n*_TCR[GTS] is set by software.
- ENET*n*_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

42.5.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the RMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set

- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

42.5.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

42.5.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[1588EN] to enable 1588 support.

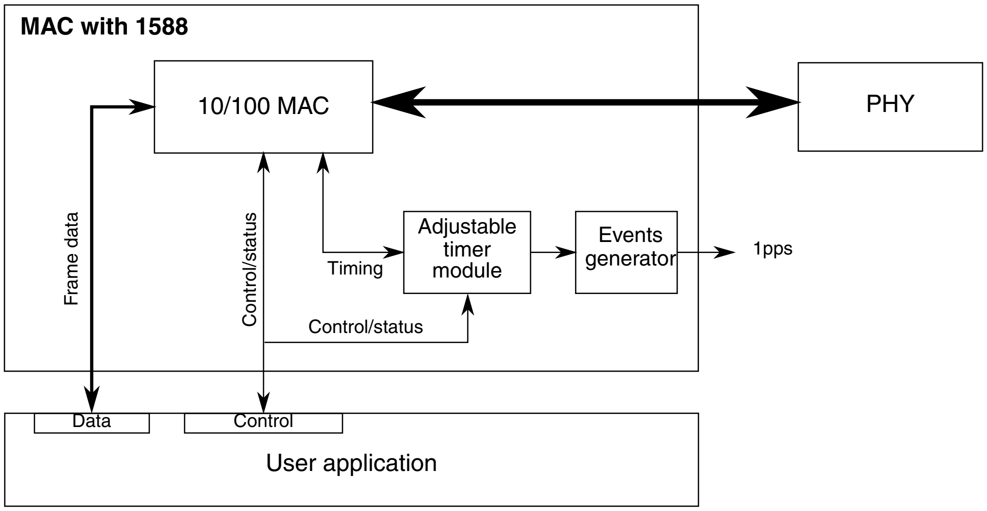

Figure 42-159. IEEE 1588 functions overview

42.5.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

ENET time-stamp clock can be sourced either externally from ENET_1588_CLKIN PAD or from inner anadig ENET PLL. However, choose a period that is an integer value (e.g. 5 ns, 6 ns, 8 ns) to implement a precise timer.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

42.5.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

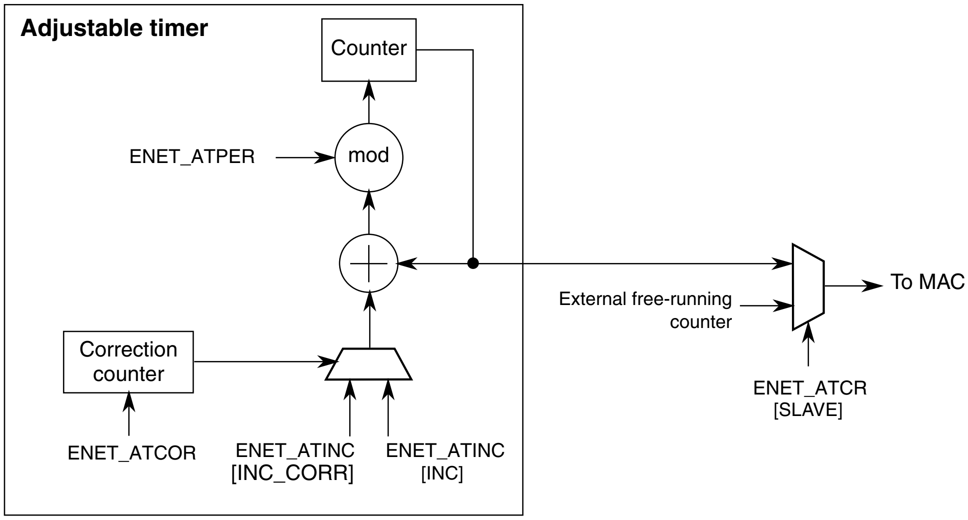

Figure 42-160. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc $-(1 \times 10^9)$), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When slave mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the master, since it is used for internal comparisons.

42.5.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

42.5.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

42.5.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to $(1 \times 10^9)-1$. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

42.5.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

42.5.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 42-183. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of six.

Table continues on the next page...

Table 42-183. Receive FIFO thresholds definition (continued)

Register	Description
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

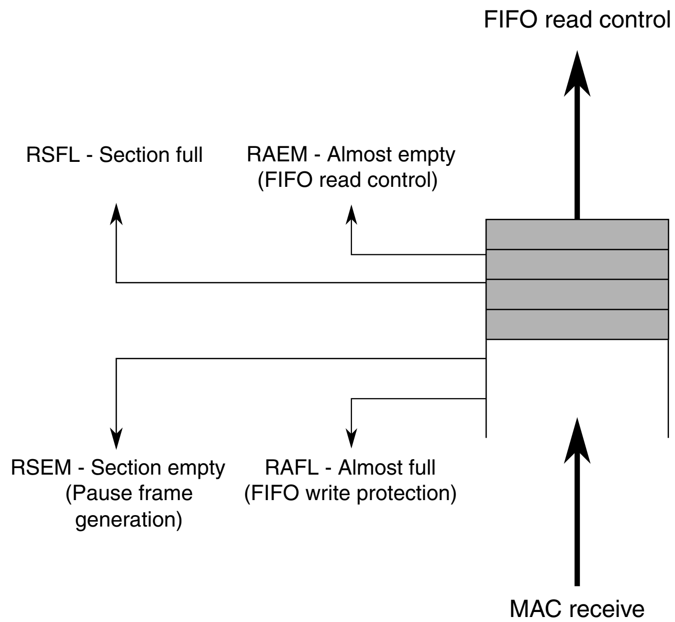

Figure 42-161. Receive FIFO overview

42.5.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 42-184. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the application an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation). If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

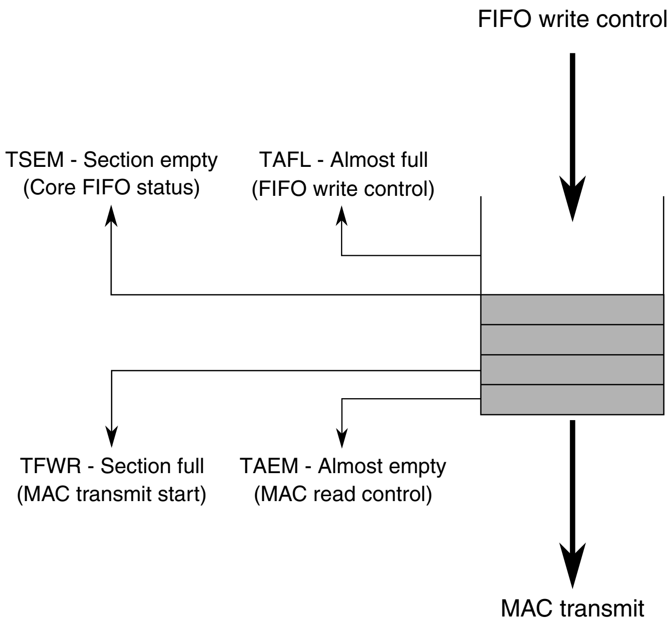

Figure 42-162. Transmit FIFO overview

42.5.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET*n*_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET*n*_RCR register fields:

Table 42-185. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

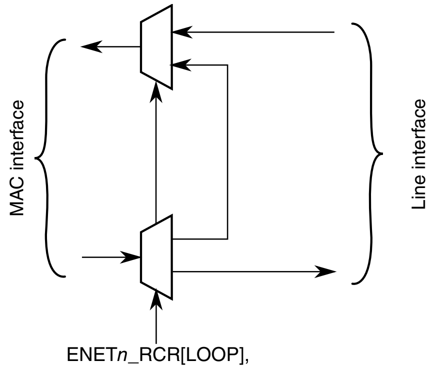

Figure 42-163. Loopback options

42.5.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENET*n*_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used only in single-ring mode, that is, when DMA*n*CFG[DMA_CLASS_EN] are zero.
- The legacy buffer descriptor tables show the byte order for little-endian chips. DBSWP must be set to 1 after reset to enable little-endian mode.

42.5.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 42-189 contains the descriptions for each field.

Table 42-186. Legacy FEC receive buffer descriptor (RxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

42.5.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. Table 42-191 contains the descriptions for each field.

Table 42-187. Legacy FEC transmit buffer descriptor (TxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data Length															
Offset + 2	R	TO1	W	TO2	L	TC	ABC[1]	—	—	—	—	—	—	—	—	—
Offset + 4	Tx Data Buffer Pointer — low halfword															
Offset + 6	Tx Data Buffer Pointer — high halfword															

1. This field is not supported by the uDMA.

42.5.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/DMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. DBSWP must be set to 1 after reset to enable little-endian mode.

42.5.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 42-189 contains the descriptions for each field.

Table 42-188. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer – low halfword															
Offset + 6	Rx data buffer pointer – high halfword															

Table continues on the next page...

Table 42-188. Enhanced uDMA receive buffer descriptor (RxBD) (continued)

Offset + 8	VPCP			—	—	—	—	—	—	—	ICE	PCR	—	VLAN	IPV6	FRAG

Table 42-189. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	15 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 2	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	11 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	10–9	Reserved, must be cleared.

Table continues on the next page...

Table 42-189. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 2	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	7 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 2	6 MC	Set if the DA is multicast and not BC.
Offset + 2	5 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 2	4 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	3	Reserved, must be cleared.
Offset + 2	2 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	1 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, CR, and CL, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	0 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	15–0 low	Receive data buffer pointer, low halfword
0ffset + 6	15–0 high	Receive data buffer pointer, high halfword[1]
Offset + 8	15–13 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + 8	12–6	Reserved, must be cleared.
Offset + 8	5 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	4 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + 8	3	Reserved, must be cleared.

Table continues on the next page...

Table 42-189. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	2 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	1 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	0 FRAG	IPv4 Fragment.This is an accelerator option.This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + A	15 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	14–11	Reserved, must be cleared.
Offset + A	10 PE	PHY Error. This field is written by the uDMA. Set to "1"when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + A	9 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	8 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	7 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the *dma_int_rxb* / *dma_int_rxfevent*.
Offset + A	6–0	Reserved, must be cleared.
Offset + C	15–0 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	15–11 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + E	10–8	Reserved, must be cleared.
Offset + E	7–0 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.

Table continues on the next page...

Table 42-189. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 14 Offset + 16	15–0 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 18 – Offset + 1E	15–0	Reserved, must be cleared.

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

42.5.14.2 Enhanced transmit buffer descriptor

Table 42-190. Enhanced transmit buffer descriptor (TxBD)

	Byte 1								Byte 0

Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 42-191. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	15–0 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.

Table continues on the next page...

Table 42-191. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 2	15 R	Ready. Written by the MAC and you. 0 — The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 — The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 2	14 TO1	Transmit software ownership. This field is reserved for software use. This read/ write field is not modified by hardware and its value does not affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 — The next buffer descriptor is found in the consecutive location 1 — The next buffer descriptor is found at the location defined in ETDSR.
Offset + 2	12 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	11 L	Last in frame. Written by user. 0 — The buffer is not the last in the transmit frame 1 — The buffer is the last in the transmit frame
Offset + 2	10 TC	Transmit CRC. Written by user, and valid only when L is set. 0 — End transmission immediately after the last data byte 1 — Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 2	9 ABC	Append bad CRC. **Note:** This field is not supported by the uDMA and is ignored.
Offset + 2	8–0	Reserved, must be cleared.
Offset + 4	15–0 low	Tx data buffer pointer, low halfword
Offset + 6	15–0 high	Tx data buffer pointer, high halfword. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 8. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller.
Offset + 8	15 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	14	Reserved, must be cleared.
Offset + 8	13 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + 8	12 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.

Table continues on the next page...

Table 42-191. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	11 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	10 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	9 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	8 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type then a timestamp frame. This field is valid only when the L field is set.
Offset + 8	7–0	Reserved, must be cleared.
Offset + A	15	Reserved, must be cleared.
Offset + A	14 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + A	13 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	12 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	11 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	10–0	Reserved, must be cleared.
Offset + C	15–0	Reserved, must be cleared.
Offset + E	15–0	Reserved, must be cleared.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14 Offset + 16	15–0 1588 timestamp	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 18–Offset + 1E	15–0	Reserved, must be cleared.

42.5.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

42.5.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 42-192. FIFO interface data structure

	63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8
...	...							

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if ENET*n*_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET*n*_PAUR and ENET*n*_PALR registers.

Table 42-193. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 42-194. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

42.5.15.2 Data structure examples

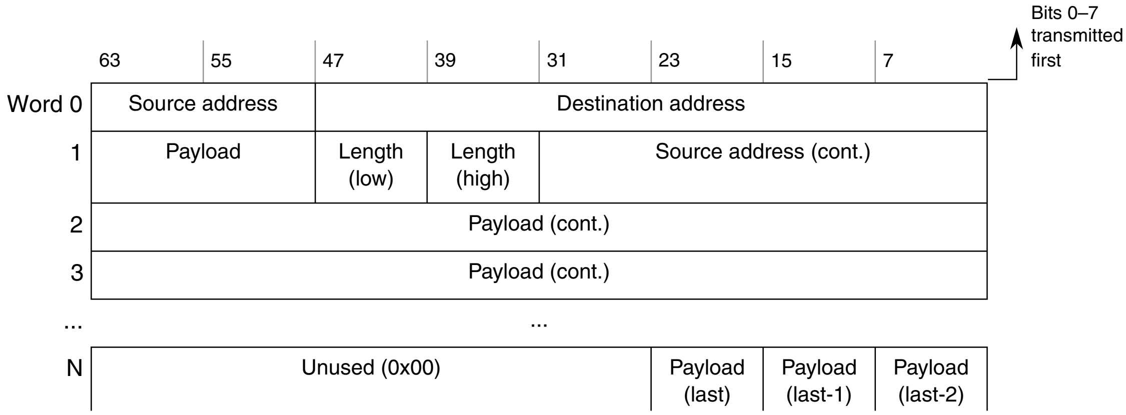

Figure 42-164. Normal Ethernet frame 64-bit mapping example

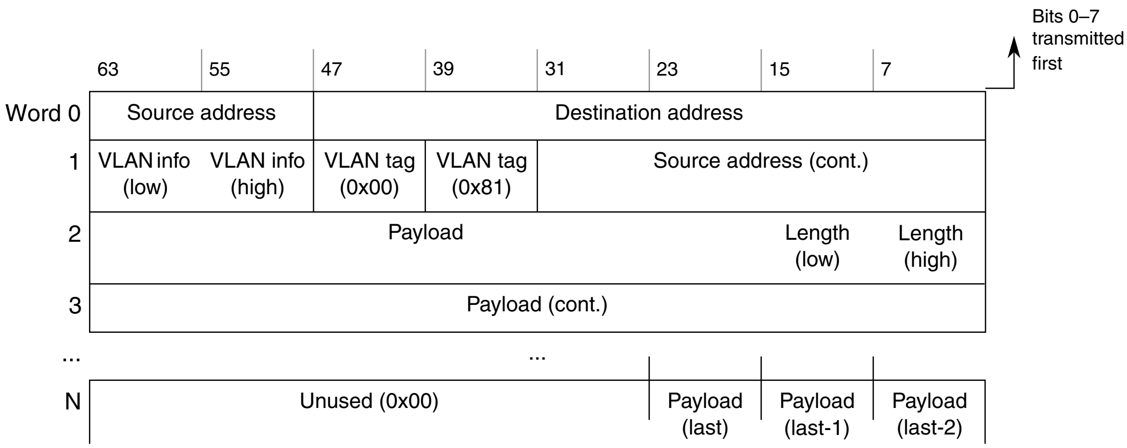

Figure 42-165. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

42.5.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See Enhanced buffer descriptors for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

42.5.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

42.5.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 42-166) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

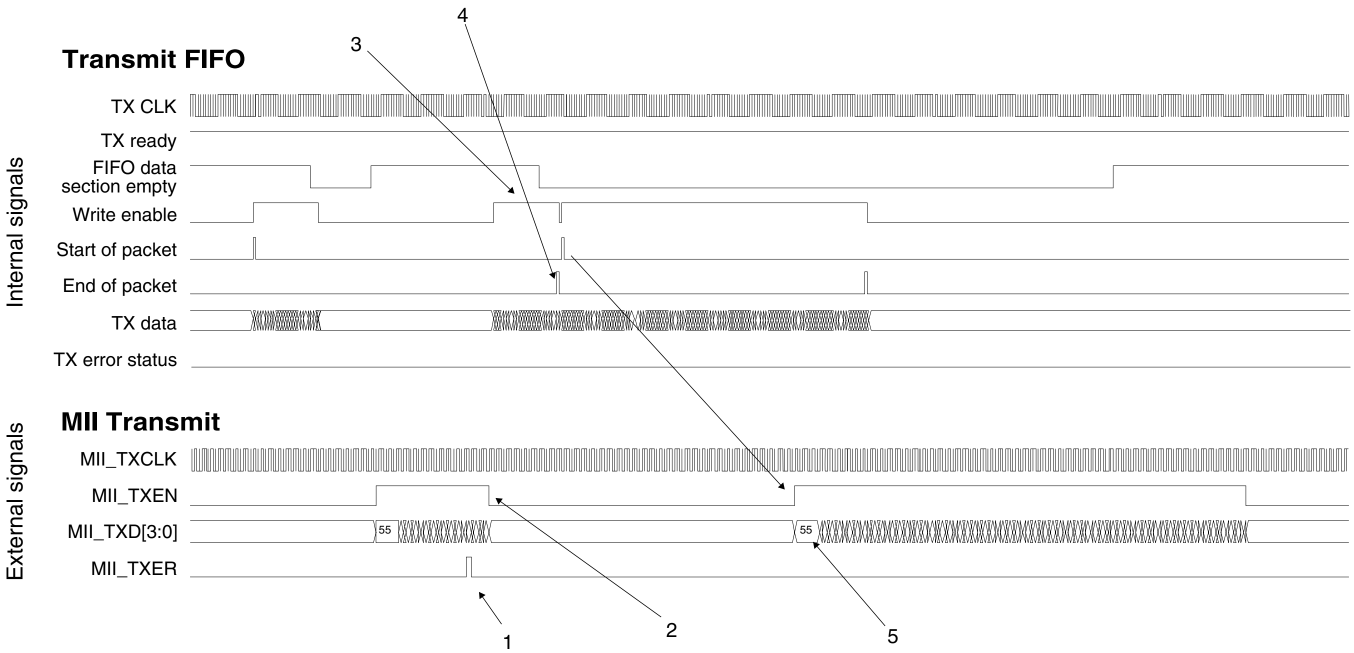

Figure 42-166. Transmit FIFO underflow protection

42.5.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET*n*_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

42.5.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

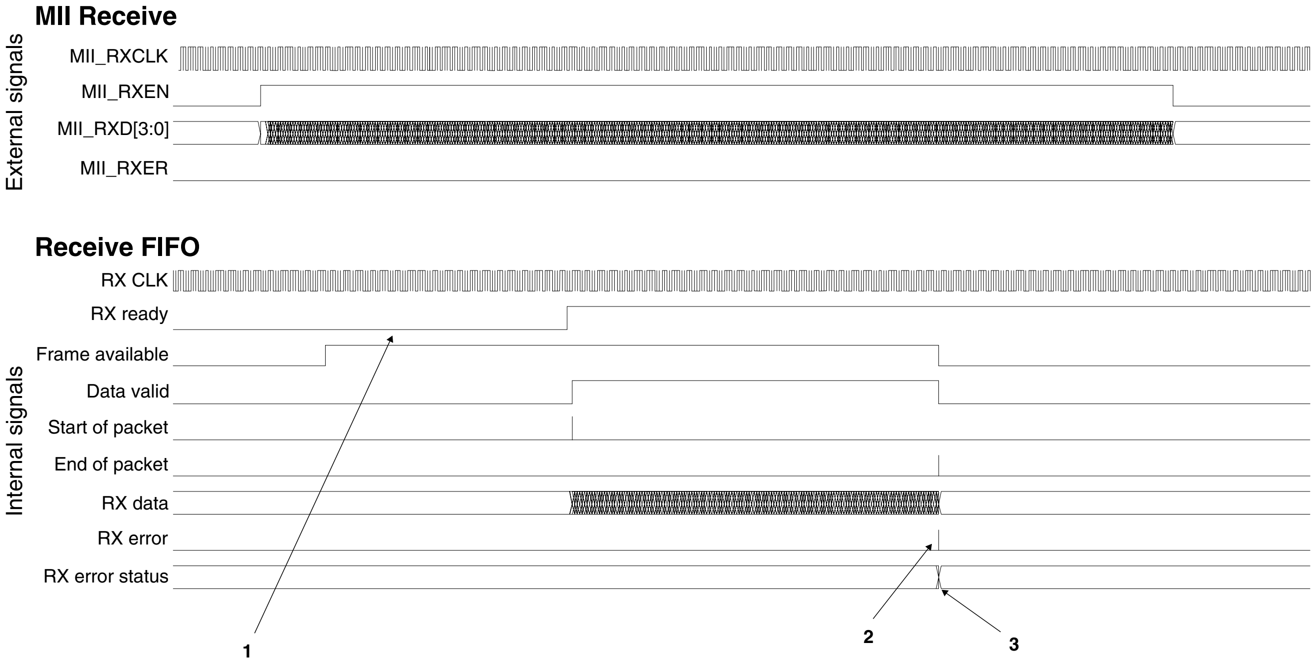

Figure 42-167. Receive FIFO overflow protection

42.5.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

Ethernet speed mode	Ethernet bus clock	Minimum ENET system clock
10 Mbps	2.5 MHz	5 MHz
100 Mbps	25.0 MHz	50 MHz

42.5.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

42.5.18.1 MDIO frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal).

The core PHY management interface supports the standard MDIO specification (IEEE803.2 Clause 22).

Table 42-195. MDIO frame formats (read/write)

Type	Command					TA	Data		Idle
	PRE	ST	OP	Addr1	Addr2		MSB	LSB	
Read	1…1	01	10	xxxxx	xxxxx	Z0	xxxxxxxxxxxxxxxx		Z
Write	1…1	01	01	xxxxx	xxxxx	10	xxxxxxxxxxxxxxxx		Z

Table 42-196. MDIO frame field descriptions

Field	Description
PRE	Preamble. 32 bits of logical ones sent prior to every transaction when ENET*n*_MSCR[DIS_PRE] is cleared. If DIS_PRE is set, the preamble is not generated.
ST	Start indication, programmed with ENET*n*_MMFR[ST] • Standard MDIO (Clause 22): 01
OP	Opcode defines if a read or write operation is performed, programmed with ENET*n*_MMFR[OP]. 01 Write operation 10 Read operation
Addr1	The PHY device address, programmed with ENET*n*_MMFR[PA]. Up to 32 devices can be addressed.
Addr2	Register address, programmed with ENET*n*_MMFR[RA]. Each PHY can implement up to 32 registers.
TA	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data	16 bits of data, set to ENET*n*_MMFR[DATA]. Written to or read from the PHY
Idle	The MDIO data signal is tri-stated between frames.

42.5.18.2 MDIO clock generation

The MDC clock is generated from the internal bus clock divided by the value programmed in ENET*n*_MSCR[MII_SPEED].

42.5.18.3 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET*n*_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENET*n*_EIR[MII] field.

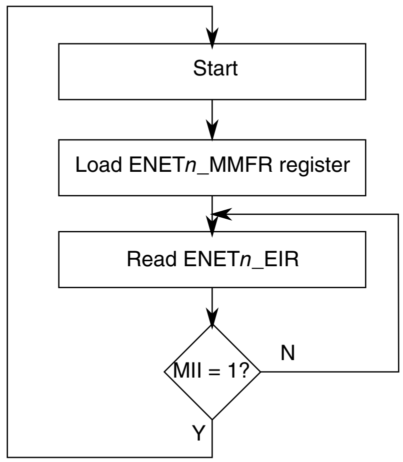

Figure 42-168. MDIO access overview

42.5.19 Ethernet interfaces

RMII 10/100 is implemented using interface converters/gaskets.

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]
RMII - 10 Mbit/s	0	1	1
RMII - 100 Mbit/s	0	0	1

42.5.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

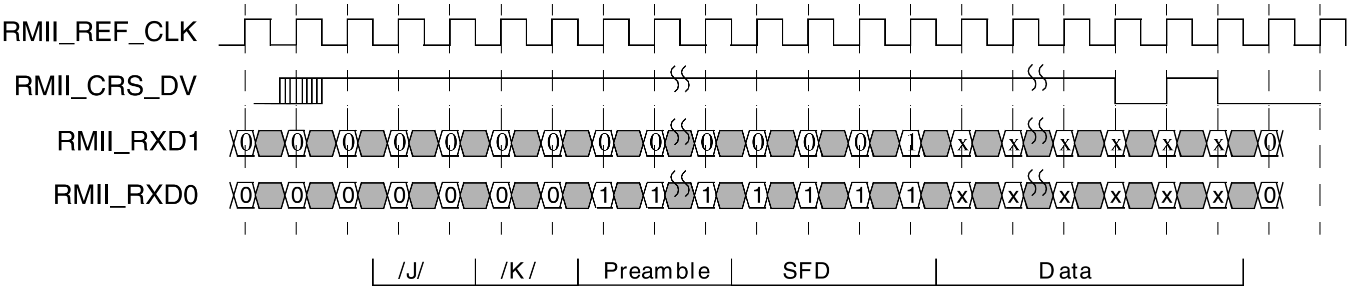

Figure 42-169. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

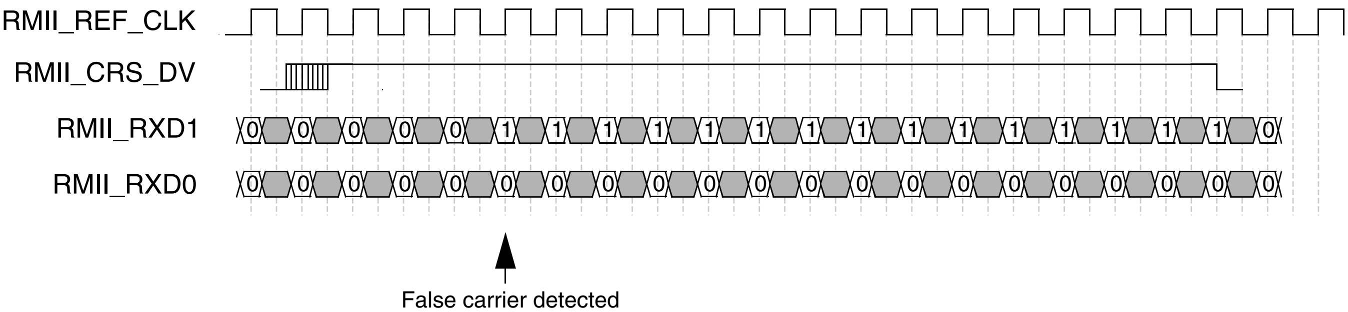

Figure 42-170. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

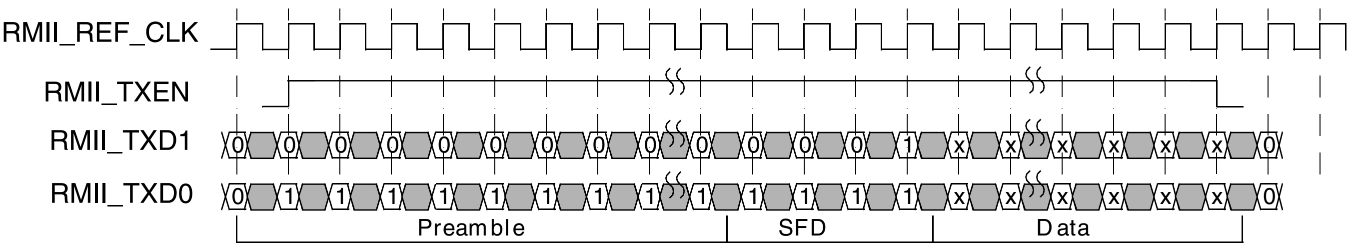

Figure 42-171. RMII transmit operation

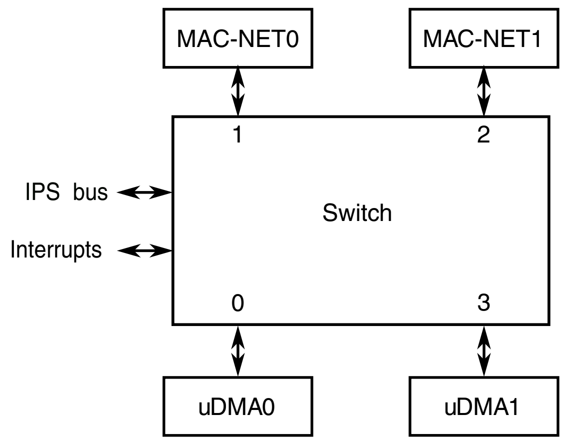
Chapter 43
Ethernet Switch (ESW)

43.1 Introduction

The switch core is seamlessly connected to the MAC-NET core and DMA controllers. For control and configuration, the switch implements a register interface and multiple maskable interrupts.



The switch port assignment is listed in Table 43-1 .

Table 43-1. Port Assignment

Switch Port	Assignment
0	DMA 0
1	MAC-NET 0
2	MAC-NET 1
3 (bypass port)	DMA 1

43.1.1 Block Diagram

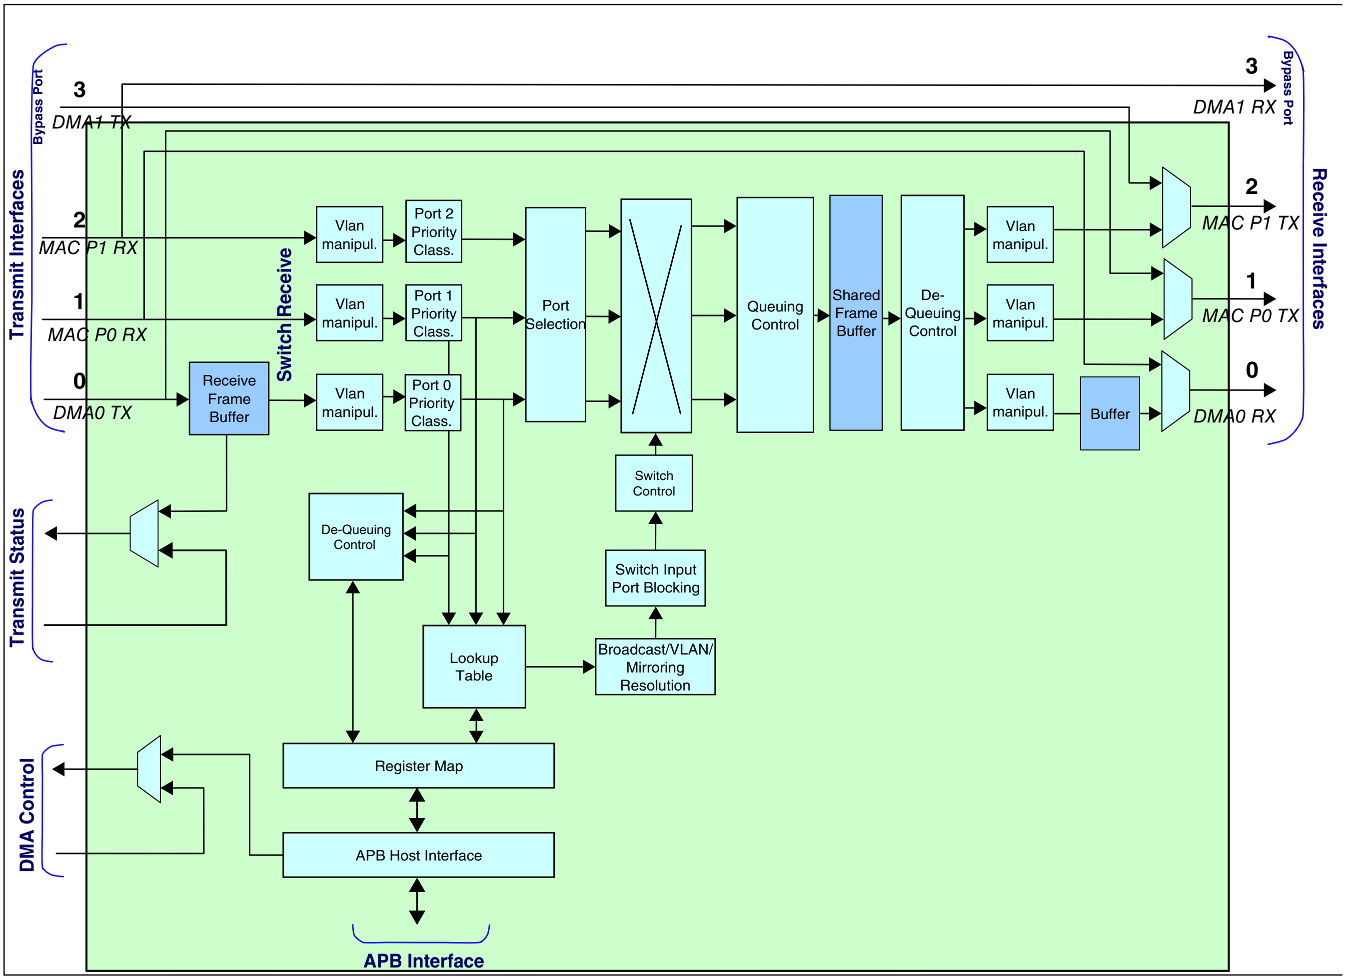


Figure 43-1. Block Diagram

Note

- The left side is termed "Transmit Interfaces" as the interfaces are driven by the DMA transmit interfaces in pass-through mode. If the switch is enabled, these interfaces connect to the switch internal receive interfaces. The right side is named "Receive Interfaces" as the interfaces represent (are driven from) the respective MAC receive interfaces in pass-through mode connected to the DMA RX. If the switch is enabled these are driven by the switch internal transmit interfaces. See Introduction for a description of the operational modes.
- All descriptions related to switch functions refer to the switch internal receive/transmit interfaces.

- Receive Frame buffer (DMA0 TX interface). Can hold at least one complete frame transferred from DMA0 to the switch. This is a local 64-bit wide FIFO to absorb a burst from the DMA, provide the necessary transaction handshake to the DMA, and forward the frame then to the switch logic.
- Decoupling buffer only (DMA0 RX interface) to absorb switch latency (e.g. 16/32 words) resulting from a rdy deassertion from DMA0.
- The APB host interface module implements an indirect addressing scheme to the internal registers to allow arbitrary length access cycles (e.g. address table read/write and configuration register read/write). However the DMA control registers are directly mapped and accessed through APB.

43.1.2 Features

- Integrated Ethernet switch engine compatible with 10/100 MAC-NET core
- Three port switch with a fourth DMA bypass port
- Can be configured to operate as a 3-port switch (switch mode) or as two independent ports (passthrough mode)
- Filters and forward traffic at wire-speed on all ports
- Per-queue tail-drop congestion management
- Implements hardware switching look-up mechanism providing a learning capacity of up to 2K MAC addresses
- Supports configurable VLAN switching when MAC address lookup should be omitted
- Classification and priority assignment based on port number, MAC address, IPv4 DiffServ code point field, IPv6 Class of Service and VLAN Priority (IEEE802.1q)
- Efficient output queue frame buffering with shared Frame buffer of 24 Kbyte
- Each port implements four priority queues with configurable weighted round-robin selection

- Support Ethernet multicast and broadcast with flooding control to avoid unnecessary duplication of frames
- Programmable multicast destination port mask to restrict frame duplication for individual multicast addresses
- Multicast and broadcast resolution with VLAN domain filtering providing a strict separation of up to 32 VLANs
- IP snooping with programmable protocol and port number registers
- Programmable ingress and egress VLAN tag addition, removal and manipulation supporting single and double-tagged VLAN frames
- Event and status signals which can monitor port activity, severe error conditions, or any user-specific event
- Programmable firmware operation with static or dynamic (learning, aging) switching tables
- Switch firmware source available to provide customer-specific software development capability
- Support for IEEE 1588 precise time-stamping applications
- Supports aggregation and redundant backplane applications

43.2 Modes of Operation

The switch can be configured to operate in the following modes using ESW_MODE[SWEN].

- Passthrough mode — The switch logic is disabled and bypassed
- Switch mode — The switch logic is enabled

43.2.1 Passthrough mode

When ESW_MODE[SWEN] is written to 0, the switch logic is bypassed and can be powered down and disabled with the switch clocks stopped and the switch reset signals asserted.

The switch APB interface and interrupt signals are disabled and should not be used. To control the frame transfer from DMA0 and DMA1, the MAC-NET 0 and the MAC-NET 1 APB interfaces and interrupt signals should be used.

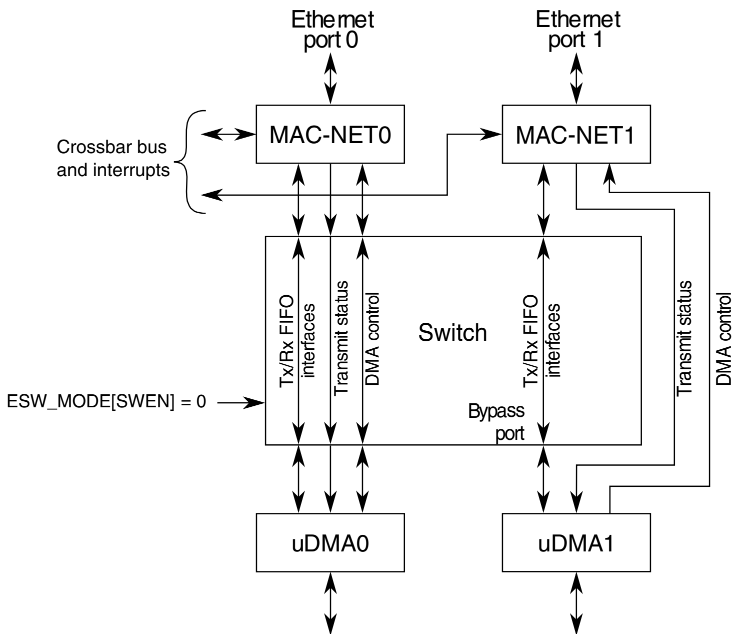

Figure 43-2. Passthrough Mode Configuration Overview

43.2.2 Switch Mode

When the switch is programmed to operate in switch mode (ESW_MODE[SWEN] set to 1), the bypass mode (port 1) interface is disabled and should not be used.

Frame transfers to and from the line are performed on port 0 only (DMA 0). The transmit status signals are generated from the switch port 0 receive buffer and the DMA control signals from the switch register space. The MAC-NET 0 and MAC-NET 1 transmit status and DMA control signals are not used.

The MAC-NET 0 and MAC-NET 1 APB interfaces and interrupts are enabled and can monitor the line activity and gather the line statistic information.

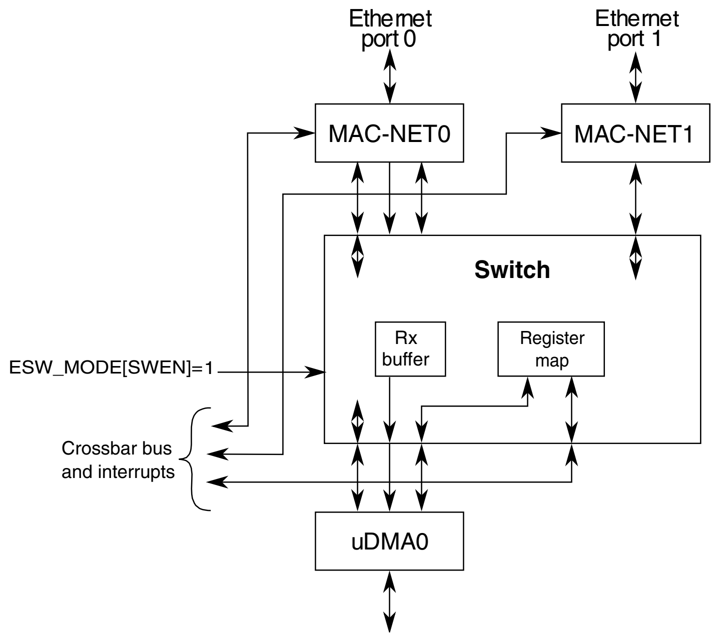

Figure 43-3. Switch Mode Configuration Overview

43.2.2.1 Port 0 Input Buffer

A dedicated input buffer of at least 2 KB storage is implemented at the port 0 (DMA 0) input interface, when the switch is operating in switch mode. In bypass mode, this buffer is bypassed.

The input buffer is normally operated in store-and-forward mode, absorbing a DMA burst and forwarding the frame to the switch (internally) when the complete frame is stored in the input buffer.

43.2.2.2 Port 0 Input Backpressure/Congestion Indication

When frames are transferred from DMA0 to the switch's port 0 transmit interface, the input buffer indicates when data is to be written to the port 0 input. When the buffer reaches an almost full threshold, it indicates a stop request to DMA0. DMA0 may write a few more words (typically up to four), and then stops writing.

In addition, a special backpressure mechanism for port 0 is included to pause DMA0 transfers when the output queues' shared memory (see Output Frame Queuing) becomes full to a programmable threshold. Respecting the output queues' shared memory fill level can avoid the switch (due to memory congestion) discarding frames written by the DMA0. The threshold is configured through ESW_P0BCT.

If the shared memory has less than ESW_P0BCT number of free cells available, the switch stops serving port 0. That is, the switch does not start to read a frame from the port 0 input buffer. The port 0 input buffer continues to accept data from DMA0 until it becomes full.

Note

The backpressure only considers the total amount of memory available, not a specific queue. Hence, it may still happen that an outgoing frame from DMA0 is discarded by the switch, if the output queue for the frame is congested while the total amount of memory has free space available.

The backpressure threshold (ESW_P0BCT) should be set higher than the memory full threshold (ESW_LMT) to stop the DMA0 before a memory full situation.

43.3 ESW memory map and registers

Table continues on the next page...

ESW_VLANV field descriptions (continued)

Field	Description
18 DU2	Discard unknown. 0 Received frames with unknown VLAN IDs are not discarded 1 Received frames with an unknown VLAN ID or no VLAN tag are discarded and not forwarded (i.e. the default bcast is ignored)
17 DU1	Discard unknown. 0 Received frames with unknown VLAN IDs are not discarded 1 Received frames with an unknown VLAN ID or no VLAN tag are discarded and not forwarded (i.e. the default bcast is ignored)
16 DU0	Discard unknown. 0 Received frames with unknown VLAN IDs are not discarded 1 Received frames with an unknown VLAN ID or no VLAN tag are discarded and not forwarded (i.e. the default bcast is ignored)
15–3 Reserved	This field is reserved. Reserved, must be cleared.
2 VV2	Verify VLAN domain. 0 Frames are routed to the output port without VLAN domain checking 1 A frame is accepted from the port as valid only when the input and output ports are members of the VLAN domain of the frame.
1 VV1	Verify VLAN domain. 0 Frames are routed to the output port without VLAN domain checking 1 A frame is accepted from the port as valid only when the input and output ports are members of the VLAN domain of the frame.
0 VV0	Verify VLAN domain. 0 Frames are routed to the output port without VLAN domain checking 1 A frame is accepted from the port as valid only when the input and output ports are members of the VLAN domain of the frame.

43.3.5 Default broadcast resolution (ESW_DBCR)

The default output port list for broadcast/flooding resolution (see Section 32.5.9.2, "Broadcast/Multicast/VLAN Domain Resolution").

Address: 400E_8000h base + 14h offset = 400E_8014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ESW_DMCR field descriptions

Field	Description
31–3 Reserved	This field is reserved. Reserved, must be cleared.
2 P2	Default multicast resolution. When the received frame carries a multicast address, the default output port list used instead of ESW_DBCR.
1 P1	Default multicast resolution. When the received frame carries a multicast address, the default output port list used instead of ESW_DBCR.
0 P0	Default multicast resolution. When the received frame carries a multicast address, the default output port list used instead of ESW_DBCR.

43.3.7 Blocking and learning enable (ESW_BKLR)

ESW_BKLR independently defines the blocking and learning states for each port.

Address: 400E_8000h base + 1Ch offset = 400E_801Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved													LD2	LD1	LD0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved													BE2	BE1	BE0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_BKLR field descriptions

Field	Description
31–19 Reserved	This field is reserved. Reserved
18 LD2	Disable learning. 0 Enable. 1 Disable. Only bridge protocol data unit frames are learned. Other frames are ignored for learning.
17 LD1	Disable learning. 0 Enable. 1 Disable. Only bridge protocol data unit frames are learned. Other frames are ignored for learning.
16 LD0	Disable learning. 0 Enable. 1 Disable. Only bridge protocol data unit frames are learned. Other frames are ignored for learning.
15–3 Reserved	This field is reserved. Reserved, must be cleared.
2 BE2	Enable blocking. 0 Disable. 1 Enable. Only bridge protocol data units are accepted on that input, all other frames are discarded.
1 BE1	Enable blocking. 0 Disable. 1 Enable. Only bridge protocol data units are accepted on that input, all other frames are discarded.
0 BE0	Enable blocking. 0 Disable. 1 Enable. Only bridge protocol data units are accepted on that input, all other frames are discarded.

43.3.8 Bridge management port configuration (ESW_BMPC)

ESW_BMPC enables and defines the management port that receives bridge protocol frames.

Address: 400E_8000h base + 20h offset = 400E_8020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved													PORTMASK		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	PRIORITY			Reserved					DIS	EN	MSGTX	Reserved	PORT			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_BMPC field descriptions

Field	Description
31–19 Reserved	This field is reserved. Reserved, must be cleared.
18–16 PORTMASK	Portmask for transmission of BPDU frames as defined in Section 32.5.9.5.4, "Management Frame Forwarding". When the management port transmits a BPDU frame to the switch, it is forwarded to all ports in this portmask (bit16=port0, bit17=port1, bit 18=port2).
15–13 PRIORITY	Priority to use for transmitted management frames. Used to e.g. put a management frame in a high-priority output queue for fast delivery.
12–8 Reserved	This field is reserved. Reserved, must be cleared.
7 DIS	If set, BPDU frames are discarded always. Setting has no effect, when the enable bit is set.
6 EN	If set, all BPDU frames are forwarded exclusively to the management port specified in bits 3:0. If cleared, BPDU frames are forwarded as any other frame, or discarded if the discard bit is set.
5 MSGTX	Set (latched) when a BPDU frame as defined in Section 32.5.9.5.4, "Management Frame Forwarding" was transmitted from the management port to any output port. Bit is reset by writing into the register.
4 Reserved	This field is reserved. Reserved, must be cleared.
3–0 PORT	The Port number of the port that should act as a management port. Relevant to all functions that forward frames to the management port (i.e. BPDU processing, snooping). Note: It must be set 0 in this switch configuration (Port 0 to DMA0 is the management port).

43.3.9 Mode configuration (ESW_MODE)

ESW_MODE defines several global configuration settings.

Address: 400E_8000h base + 24h offset = 400E_8024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	STATRST	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved						P0CT	CRCTRAN	STOP	Reserved					SWEN	SWRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_MODE field descriptions

Field	Description
31 STATRST	Reset Statistics Counters Command. When set during a write, all statistics counters are cleared. When set, all other bits are ignored and do not influence the currently stored value in the register (i.e. it is not necessary to read/preserve the register contents prior to writing this bit).
30–10 Reserved	This field is reserved. Reserved, must be cleared.
9 P0CT	Enable Port0 input buffer cut-through mode. When cleared (0, default) the input buffer operates in store&forward mode, which is the recommended mode of operation.
8 CRCTRAN	When enabled (1) the MAC ports are expected to process frames to/from the switch including CRC.
7 STOP	Controls toplevel output pin stop_en. No internal function.
6–2 Reserved	This field is reserved. Reserved, must be cleared.
1 SWEN	Controls toplevel output pin switch_en. When deasserted (0), all DMA registers are cleared.
0 SWRST	Controls toplevel output pin switch_reset. No internal function.

43.3.10 VLAN input manipulation select (ESW_VIMSEL)

ESW_VIMSEL defines behavior of the VLAN input manipulation function, if such a function is present on an input port. ESW_VIMSEL has effect only if enabled by the corresponding port bit in ESW_VIMEN.

Address: 400E_8000h base + 28h offset = 400E_8028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESW_MCVAL field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved, must be cleared.
7–0 COUNT	Count value for mirror filtering. Every n^{th} frame is forwarded to the mirror port, if enabled. 0x00 Every frame forwarded 0x01 Every frame forwarded

Table continues on the next page...

ESW_MCVAL field descriptions (continued)

Field	Description
	0x02 Every second frame forwarded ... 0xFF Every 255 th frame forwarded

43.3.26 Memory manager status (ESW_MMSR)

All latched bits are cleared upon a write with any content to the register.

Address: 400E_8000h base + 80h offset = 400E_8080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved								CELLS_AVAIL							
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved									DQGRNT	Reserved		MFLATCH	MEMFULL	NOCELL	BUSY
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0

ESW_MMSR field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved, must be cleared.
23–16 CELLS_AVAIL	Real-time indication of currently available cells in memory.
15–7 Reserved	This field is reserved. Reserved, must be cleared.
6 DQGRNT	Indication of if currently inputs are de-queued. Should be set always and is cleared when the memory becomes full (see the MEMFULL bit). **NOTE:** The bit is cleared upon reset. However, set shortly after when the memory manager completes initialization.
5–4 Reserved	This field is reserved. Reserved, must be cleared.
3 MFLATCH	Latched version of mem_full. Is kept set even when mem_full is cleared again. The bit is cleared when the register is written.

Table continues on the next page...

ESW_MMSR field descriptions (continued)

Field	Description
2 MEMFULL	Current memory full indication. The memory is full when less than the programmed minimum cell threshold is available in memory. This is not an error and the memory controller is working fine. It just indicates that the switch does no longer serve its input ports to avoid memory overrun (no_cell error).
1 NOCELL	Set, when memory has exceeded the maximum available number of cells. The event is latched and the bit stays set if the event is no longer active. This is a fatal error and must never happen during operation. The minimum cells threshold must be increased if it happens.The bit is always set after reset (during initialization) and must be cleared when the busy initialization (see bit 0) indication is cleared. **NOTE:** When this bit is set any time during operation (after initialization completed) the switch is in an inoperable state and must be reset completely to restore correct operation. If such an event happens the ESW_LMT setting must be increased during initialization to avoid such situation. The bit is cleared when the register is written.
0 BUSY	When set (1), Memory controller is initializing. The initialization is only preparing the internal data structures within the controller, it does not initialize the shared memory used for frame storage as this is not required. It is asserted after reset and stays set until the memory controller is ready to store frames. The switch must not be enabled before initialization of the memory controller has been completed.

43.3.27 Low memory threshold (ESW_LMT)

If the number of cells available in memory is less than ESW_LMT, the switch discards frames. Choose a value for at least two full-sized frames. A memory overflow due to a too low threshold is a fatal error and may require a device reset.

Address: 400E_8000h base + 84h offset = 400E_8084h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESW_LMT field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved, must be cleared.
7–0 THRESH	Low memory threshold. The value of this field is the number of 256 bytes. 0x01 0.25 KB (1 x 256 bytes) 0x02 0.5 KB (2 x 256 bytes) ... 0x09 2.25 KB (9 x 256 bytes) ... **NOTE:** Choose a value for at least two full-sized frames.

43.3.28 Lowest number of free cells (ESW_LFC)

ESW_LFC indicates the lowest number of free cells reached in memory during operation since it was last cleared.

Address: 400E_8000h base + 88h offset = 400E_8088h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
	0 Not ready 1 Ready
0 OR0	Output ready to accept data for port 0. 0 Not ready 1 Ready

43.3.31 Queue weights (ESW_QWT)

ESW_QWT defines the weight for the corresponding queue for all ports. Setting all weights to zero implements a strict priority scheme.

Address: 400E_8000h base + 94h offset = 400E_8094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved			Q3WT					Reserved			Q2WT					Reserved			Q1WT					Reserved			Q0WT				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_QWT field descriptions

Field	Description
31–29 Reserved	This field is reserved. Reserved, must be cleared
28–24 Q3WT	Queue 3 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Queue 3 is the highest priority queue. Valid values are 0-30.
23–21 Reserved	This field is reserved. Reserved, must be cleared
20–16 Q2WT	Queue 2 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Valid values are 0-30.
15–13 Reserved	This field is reserved. Reserved, must be cleared
12–8 Q1WT	Queue 1 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Valid values are 0-30.
7–5 Reserved	This field is reserved. Reserved, must be cleared
4–0 Q0WT	Queue 2 weight. Defines the weight for the corresponding queue for all ports. A higher weight gives more priority to the queue. Valid values are 0-30.

43.3.32 Port 0 Backpressure Congestion Threshold (ESW_P0BCT)

ESW_P0BCT defines the congestion threshold for port 0 backpressure. If the total output queues' shared memory (see Output Frame Queuing) has less than this number of free cells available, the switch stops serving the port 0 input buffer. This eventually fills the input buffer .

Address: 400E_8000h base + 9Ch offset = 400E_809Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																								THRESH							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1

ESW_P0BCT field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved, must be cleared.
7–0 THRESH	Defines the congestion threshold for port 0 backpressure. Clearing this field disables the function (no backpressure). **NOTE:** THRESH must be greater than the memory full threshold, ESW_LMT, to stop the DMA0 before a memory full situation. The recommended value for THRESH is 0x40, which will eliminate or minimize the number of frames discarded in the ESW due to congestion.

43.3.33 Port 0 forced forwarding enable (ESW_FFEN)

ESW_FFEN forces forwarding for port 0 frames (i.e. frames transmitted from the DMA0 to the port 0 of the switch).

Address: 400E_8000h base + BCh offset = 400E_80BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved												FD		Reserved	FEN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_FFEN field descriptions

Field	Description
31–4 Reserved	This field is reserved. Reserved, must be cleared.
3–2 FD	When FEN is set, this field defines if the port 0 frame should be forwarded to the MAC at ports 1 and 2. **NOTE:** It is possible to forward to one or both MAC ports. If neither bit is set, FEN is ignored and the frame is processed normally. This can be used to implement a handshake, as FEN is still reset but no further action occurs. 00 Do not forward. Frame is processed normally. 01 Forward to port 1 only 10 Forward to port 2 only 11 Forward to both ports
1 Reserved	This field is reserved. Reserved, must be cleared.
0 FEN	When set, the next frame received from port 0 (the local DMA port) is forwarded to the ports defined in FD. The bit resets to zero automatically when one frame from port 0 has been processed by the switch (i.e. has been read from the port 0 input buffer; see Figure 32-1). Therefore, the bit must be set again as necessary. See alsoSection 32.5.8.2, "Forced Forwarding" for a description.

43.3.34 Port snooping registers (ESW_PSNP1)

ESW_PSNP1 defines the TCP/UDP port number snooping function configuration.

Address: 400E_8000h base + C0h offset = 400E_80C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PORT_COMPARE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved											CS	CD	MODE		EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_PSNP1 field descriptions

Field	Description
31–16 PORT_ COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. Reserved, must be cleared.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value. **NOTE:** The management port is defined in ESW_BMPC register. 00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

43.3.35 Port snooping registers (ESW_PSNP2)

ESW_PSNP2 defines the TCP/UDP port number snooping function configuration.

Address: 400E_8000h base + C4h offset = 400E_80C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–16 PORT_ COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. Reserved, must be cleared.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value. **NOTE:** The management port is defined in ESW_BMPC register. 00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

43.3.37 Port snooping registers (ESW_PSNP4)

ESW_PSNP4 defines the TCP/UDP port number snooping function configuration.

Address: 400E_8000h base + CCh offset = 400E_80CCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	PORT_COMPARE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved											CS	CD	MODE		EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_PSNP4 field descriptions

Field	Description
31–16 PORT_ COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. Reserved, must be cleared.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value. **NOTE:** The management port is defined in ESW_BMPC register. 00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

43.3.38 Port snooping registers (ESW_PSNP5)

ESW_PSNP5 defines the TCP/UDP port number snooping function configuration.

Address: 400E_8000h base + D0h offset = 400E_80D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PORT_COMPARE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved											CS	CD	MODE		EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_PSNP5 field descriptions

Field	Description
31–16 PORT_ COMPARE	The 16-bit port number to compare within the TCP or UDP header of a frame. Note: it is possible to set both the compare source/dest bits. The result is OR'ed, meaning if any of the fields match the compare value, the frame is processed as defined by the mode bits.
15–5 Reserved	This field is reserved. Reserved, must be cleared.
4 CS	When set, the TCP or UDP source port number field within the frame is compared with the compare value provided in 31:16.
3 CD	When set, the TCP or UDP destination port number field within the frame is compared with the compare value provided in PORT_COMPARE.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value. **NOTE:** The management port is defined in ESW_BMPC register. 00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the TCP/UDP destination port value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the snooping function only if the enable bit is set. Otherwise the settings are ignored. When written with 0 will also force bits 3,4 to 0. Defaults to 0 upon reset.

43.3.39 Port snooping registers (ESW_PSNP6)

ESW_PSNP6 defines the TCP/UDP port number snooping function configuration.

Address: 400E_8000h base + D4h offset = 400E_80D4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ESW_IPSNP8 field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved, must be cleared.
15–8 PROTOCOL	The 8-bit protocol value to match with the incoming frame's IP header protocol field.
7–3 Reserved	This field is reserved. Reserved, must be cleared.
2–1 MODE	Defines the forwarding that should occur, when an IP frame is received and the protocol field matches the protocol value (see the PROTOTCOL bits). **NOTE:** The management port is defined in register ESW_BMPC. 00 Forward frame to designated management port only 01 Copy to management port and forward normally 10 Discard 11 Reserved
0 EN	When set (1) the entry contains valid data and the function is active. If a match with the protocol value occurs, the frame is processed as defined by the mode setting. All other bits of the register are interpreted by the IP snooping function only if the enable bit is set. Otherwise the settings are ignored. Defaults to 0 upon reset.

43.3.50 Port 0 VLAN priority resolution map (ESW_P0VRES)

The ESW_P0VRES register implements a 3-bit to 3-bit VLAN priority mapping capability. The current frame's 3-bit VLAN priority field is used as an index and the corresponding priority is taken from the respective position of the register giving the final classification for the frame.

Address: 400E_8000h base + 100h offset = 400E_8100h

Bit	31–24	23–21	20–18	17–15	14–12	11–9	8–6	5–3	2–0
R/W	Reserved	PRI7	PRI6	PRI5	PRI4	PRI3	PRI2	PRI1	PRI0

ESW_P0VRES field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved, must be cleared.
23–21 PRI7	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI7 field to give the final priority classification for the frame.
20–18 PRI6	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI6 field to give the final priority classification for the frame.
17–15 PRI5	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI5 field to give the final priority classification for the frame.
14–12 PRI4	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI4 field to give the final priority classification for the frame.
11–9 PRI3	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI3 field to give the final priority classification for the frame.
8–6 PRI2	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI2 field to give the final priority classification for the frame.
5–3 PRI1	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI1 field to give the final priority classification for the frame.
2–0 PRI0	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI0 field to give the final priority classification for the frame.

43.3.51 Port 1 VLAN priority resolution map (ESW_P1VRES)

The ESW_P1VRES register implements a 3-bit to 3-bit VLAN priority mapping capability. The current frame's 3-bit VLAN priority field is used as an index and the corresponding priority is taken from the respective position of the register giving the final classification for the frame.

Address: 400E_8000h base + 104h offset = 400E_8104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–24 Reserved	This field is reserved. Reserved, must be cleared.
23–21 PRI7	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI7 field to give the final priority classification for the frame.
20–18 PRI6	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI6 field to give the final priority classification for the frame.
17–15 PRI5	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI5 field to give the final priority classification for the frame.
14–12 PRI4	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI4 field to give the final priority classification for the frame.
11–9 PRI3	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI3 field to give the final priority classification for the frame.
8–6 PRI2	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI2 field to give the final priority classification for the frame.
5–3 PRI1	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI1 field to give the final priority classification for the frame.
2–0 PRI0	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI0 field to give the final priority classification for the frame.

43.3.52 Port 2 VLAN priority resolution map (ESW_P2VRES)

The ESW_P2VRES register implements a 3-bit to 3-bit VLAN priority mapping capability. The current frame's 3-bit VLAN priority field is used as an index and the corresponding priority is taken from the respective position of the register giving the final classification for the frame.

Address: 400E_8000h base + 108h offset = 400E_8108h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_P2VRES field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved, must be cleared.
23–21 PRI7	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI7 field to give the final priority classification for the frame.
20–18 PRI6	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI6 field to give the final priority classification for the frame.
17–15 PRI5	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI5 field to give the final priority classification for the frame.
14–12 PRI4	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI4 field to give the final priority classification for the frame.
11–9 PRI3	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI3 field to give the final priority classification for the frame.
8–6 PRI2	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI2 field to give the final priority classification for the frame.
5–3 PRI1	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI1 field to give the final priority classification for the frame.
2–0 PRI0	The current frame's 3-bit VLAN priority field is an index to the corresponding PRI0 field to give the final priority classification for the frame.

43.3.53 IPv4/v6 priority resolution table (ESW_IPRES)

Address: 400E_8000h base + 140h offset = 400E_8140h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	READ	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved	PRI2		PRI1		PRI0		IPV4SEL	ADDRESS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_IPRES field descriptions

Field	Description
31 READ	Must be cleared to write values in the tables. When set during register writes, the IPv6 select and address bits are stored in the register only and the priority bits are ignored and not written into the addressed table. When the register is read, the priority bits represent the value read from the table always.
30–15 Reserved	This field is reserved. Reserved, must be cleared.
14–13 PRI2	The priority information to write into the addressed table entry. These 2 bits represent the output priority selected when the frame is received on port 2. When reading from the register, the bits show the value from the addressed table entry (address from last write operation).
12–11 PRI1	The priority information to write into the addressed table entry. These 2 bits represent the output priority selected when the frame is received on port 1. When reading from the register, the bits show the value from the addressed table entry (address from last write operation).
10–9 PRI0	The priority information to write into the addressed table entry. These 2 bits represent the output priority selected when the frame is received on port 0. 00=priority 0 (will be forwarded to output queue 0) 01=priority 1 (output queue 1) 10=priority 2 (output queue 2) 11=priority 3 (output queue 3) When reading from the register, the bits show the value from the addressed table entry (address from last write operation).
8 IPV4SEL	If set during a write, the IPv4 table is accessed. Valid address values range from 0 to 63. If cleared, the IPv6 table is accessed. Valid address values range from 0 to 255.
7–0 ADDRESS	The address of the priority entry to read or write for a frame received on port n. The IPv4 priority table has 64 entries. The IPv6 table has 256 entries. See also Section 32.5.5.2.1, "Classification Table Programming Model" for a description of the mapping table.

43.3.54 Port 0 priority resolution configuration (ESW_P0RES)

ESW_P0RES defines which priority information should be used for priority resolution.

Address: 400E_8000h base + 180h offset = 400E_8180h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved									DFLT_PRI			Reserved	MAC	IP	VLAN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_P0RES field descriptions

Field	Description
31–7 Reserved	This field is reserved. Reserved, must be cleared.
6–4 DFLT_PRI	The default priority of a frame received on port n, if none of the priority resolutions could define a priority of the frame. Up to 3 bits can be implemented.
3 Reserved	This field is reserved. Reserved, must be cleared.
2 MAC	Enable MAC based priority resolution for frame received on port n. If set, the priority information found within the MAC address table is used.
1 IP	Enable IP priority resolution for frame received on port n. If set, the IP DiffServ/COS field is used and priority is resolved according to the ESW_IPRES setting for the port. If cleared, IP Diffserv/COS fields are ignored.
0 VLAN	Enable VLAN priority resolution for frame received on port n. If set, the VLAN tag field of a frame is inspected and priority is resolved according to the setting programmed in ESW_P *n* VRES for the port on which the frame was received. If cleared, VLAN priority is ignored.

43.3.55 Port 1 priority resolution configuration (ESW_P1RES)

ESW_P1RES defines which priority information should be used for priority resolution.

Address: 400E_8000h base + 184h offset = 400E_8184h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved

ESW_ISR field descriptions

Field	Description
31–10 Reserved	This field is reserved. Reserved, must be cleared.
9 LRN	Learning Record available in registers LNR_REC_0 and LNR_REC_1 . Note: this interrupt can be very frequent on a heavy loaded network. It is not recommended to use this interrupt source as interrupt but rather implement a slow background task polling the bit to perform learning.
8 OD2	Outgoing frames discarded due to output Queue congestion on Port 2 or port is disabled (ESW_PER).
7 OD1	Outgoing frames discarded due to output Queue congestion on Port 1or port is disabled (ESW_PER).
6 OD0	Outgoing frames discarded due to output Queue congestion on Port 0 or port is disabled (ESW_PER).
5 QM	Low Memory Threshold. Asserted if the memory became congested and number of free cells dropped below threshold ESW_LMT . **NOTE:** This field will become asserted after reset immediately due to memory initialization.
4 TXF	Transmit frame interrupt. This bit indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated .
3 TXB	Transmit buffer interrupt. This bit indicates a transmit buffer descriptor has been updated .
2 RXF	Receive frame interrupt. This bit indicates a frame has been received and the last corresponding buffer descriptor has been updated .
1 RXB	Receive buffer interrupt. This bit indicates a receive buffer descriptor not the last in the frame has been updated .
0 EBERR	Ethernet bus error. This bit indicates a system bus error occurs when a DMA transaction is underway .

43.3.109 Interrupt mask register (ESW_IMR)

Address: 400E_8000h base + 404h offset = 400E_8404h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESW_IMR field descriptions

Field	Description
31–10 Reserved	This field is reserved. Reserved, must be cleared.
9 LRN	Ths bit corresponds to the ESW_ISR[LRN] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[LRN] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
8 OD2	Ths bit corresponds to the ESW_ISR[OD2] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[OD2] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
7 OD1	Ths bit corresponds to the ESW_ISR[OD1] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[OD1] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
6 OD0	Ths bit corresponds to the ESW_ISR[OD0] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[OD0] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
5 QM	Ths bit corresponds to the ESW_ISR[QM] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[QM] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
4 TXF	Ths bit corresponds to the ESW_ISR[TXF] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[TXF] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
3 TXB	Ths bit corresponds to the ESW_ISR[TXB] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[TXB] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
2 RXF	Ths bit corresponds to the ESW_ISR[RXF] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[RXF] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .

Table continues on the next page...

ESW_IMR field descriptions (continued)

Field	Description
1 RXB	Ths bit corresponds to the ESW_ISR[RXB] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[RXB] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .
0 EBERR	Ths bit corresponds to the ESW_ISR[EBERR] interrupt source and determines whether the interrupt condition can generate an interrupt. At each processor clock, ESW_ISR samples the signal generated by the interrupting source. ESW_ISR[EBERR] reflects the state of the interrupt signal even if this bit is masked. 0 The interrupt source is masked 1 The interrupt source is not masked and an interrupt can occur .

43.3.110 Receive descriptor ring pointer (ESW_RDSR)

ESW_RDSR points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16).This register is not reset and must be initialized prior to operation.

Address: 400E_8000h base + 408h offset = 400E_8408h

ESW_RDSR field descriptions

Field	Description
31–2 ADDRESS	Pointer to start of receive buffer descriptor queue.
1–0 Reserved	This field is reserved. Reserved, must be cleared.

43.3.111 Transmit descriptor ring pointer (ESW_TDSR)

ESW_TSDR provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 400E_8000h base + 40Ch offset = 400E_840Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ESW_TDSR field descriptions

Field	Description
31–2 ADDRESS	Pointer to start of transmit buffer descriptor queue.
1–0 Reserved	This field is reserved. Reserved, must be cleared.

43.3.112 Maximum receive buffer size (ESW_MRBR)

The ESW_MRBR dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, ESW_MRBR must be set to ENET *n* _RCR[MAX_FL] or larger. To properly align the buffer, ESW_MRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low.

To minimize bus utilization (descriptor fetches), it is recommended that ESW_MRBR be greater than or equal to 256 bytes.

The ESW_MRBR register is undefined at reset and must be initialized by the user.

Address: 400E_8000h base + 410h offset = 400E_8410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESW_MRBR field descriptions

Field	Description
31–14 Reserved	This field is reserved. Reserved, must be cleared.
13–4 SIZE	Maximum size of receive buffer size in bytes. To minimize bus utilization (descriptor fetches), set this field to 256 bytes (0x10) or larger. 0x010 256 + 15 bytes (minimum size recommended) 0x011 272 + 15 bytes ... 0x3FF 16,368 + 15 bytes
3–0 Reserved	This field is reserved. Reserved, must be cleared.

43.3.113 Receive descriptor active (ESW_RDAR)

ESW_RDAR is a command register, written by the user, indicating the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (provided ENET *n* _ECR[ETHER_EN] is also set). After the MAC polls a receive descriptor whose empty bit is not set, the MAC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

The ESW_RDAR register is cleared at reset and when ENET *n* _ECR[ETHER_EN] is cleared.

Address: 400E_8000h base + 414h offset = 400E_8414h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–25 Reserved	This field is reserved. Reserved, must be cleared.
24 RDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC device when no additional empty descriptors remain in the receive ring. Also cleared when ENET *n* _ECR[ETHER_EN] is cleared.
23–0 Reserved	This field is reserved. Reserved, must be cleared.

43.3.114 Transmit descriptor active (ESW_TDAR)

The ENET *n* _TDAR are command registers which the user writes to indicate the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR bit is set. This value is independent of the data actually written by the user. When set, the MAC polls the transmit descriptor ring and processes transmit frames (provided ENET *n* _ECR[ETHER_EN] is also set). After the MAC polls a transmit descriptor that is a ready bit not set, MAC clears TDAR and ceases transmit descriptor ring polling until you set the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

The ENETn_TDAR registers are cleared at reset, when ENET *n* _ECR[ETHER_EN] is cleared, or when ENETn_ECR[RESET] is set.

Address: 400E_8000h base + 418h offset = 400E_8418h

43.4 MAC address lookup table

The MAC Address Lookup Table contains 2048 MAC address lookup entries. Each entry is 64 bits. The table is implemented as 32-bit registers, so each 64-bit entry is split into two 32-bit words. The low address (ADDRL) represents the lower 32 bits (31:0). The high address (ADDRH) represents the higher 32 bits (63:32) of an entry. See Address Memory for the structure of a 64-bit entry.

Each entry must be written or read with the low address accessed first followed by the high address. The table should be initialized by software during system startup.

MAC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	MAC Address Lookup Entry Low (MAC_ADDRL)	32	R/W	Undefined	43.4.1/2111
4	MAC Address Lookup Entry High (MAC_ADDRH)	32	R/W	Undefined	43.4.2/2112

43.4.1 MAC Address Lookup Entry Low (MAC_ADDRL)

Address: 0h base + 0h offset = 0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MAC_ADDRH*n* field descriptions

Field	Description
31–0 HIGH32	Higher 32 bits of MAC address lookup entry This register must be written or read after the corresponding ADDRL register.

43.5 Functional Description

The switch implements the following main functions:

- Input/output VLAN processing
- IP snooping
- Input frame parsing and priority extraction
- Input port selection
- Output port(s) resolution
- Frame queuing
- Output queue scheduling

43.5.1 VLAN Input Processing Function

The VLAN input processing function is used on each switch input port to inspect and manipulate the VLAN tag of frames entering the switch. It performs the following functions:

- Input frame parsing
- VLAN tag insertion or manipulation

Based on the information of the input processing function the frame can be switched to the corresponding output port or is discarded.

43.5.1.1 Terms and Definitions

- VLAN information — The 16-bit field following the VLAN type field within a frame
- VLAN ID — The lower 12 bits of the VLAN information field
- VLAN priority — The upper 3 bits of the VLAN information field that prioritizes incoming frames. A value of 0 represents lowest priority; a value of 7 represents highest priority.

43.5.1.2 Configuration Information

The switch management provides the following information to configure and control the operation of the function:

- ESW_P*n*ID — 16 bit value. The VLAN information field (VLAN-ID and priority) used for tag insertion operations.
- Mode of operation —There are different modes of operation, which define how incoming frames must be processed for a port. The function can be enabled and configured individually per port. See the ESW_VIMEN and ESW_VIMSEL registers.

Note

If the VLAN input processing function is not enabled (ESW_VIMEN = 0) the mode setting has no effect.

43.5.1.3 Modes of Operation

43.5.1.3.1 Frame Processing

The VLAN input processing function modifies the frames before they enter the switching engine. If a VLAN tag is inserted, the switch only acts on the inserted VLAN tag (e.g. priority). Any original tag that was found in the frame before the modification, if any, has no effect within the switch.

In addition, if VLAN verification is enabled for a port (see the ESW_VLANV register), the VLAN ID used for insertion (ESW_P*n*ID) must also be configured in the global VLAN resolution table (see the ESW_VRES*n* register). This ensures the switch accepts frames, which contain the inserted tag.

When a tag is inserted in any of the modes, it is always inserted as the first tag (outer) and its information field is set as programmed in the ESW_P*n*ID register for the port *n* where the frame is received.

43.5.1.3.2 Mode 1 — Single Tagging with Passthrough

Mode 1 inserts a tag only if the frame is untagged. If the frame is already tagged, the frame is unmodified.

43.5.1.3.3 Mode 2 — Single Tagging with Replace

If untagged, add the tag. If single tagged, overwrite it.

43.5.1.3.4 Mode 3 — Double Tagging with Passthrough

Insert a tag on untagged and tagged frames. This results in a single-tagged frame when an untagged is received, and a double-tagged frame, when a single-tagged frame is received. When a double-tagged frame is received, the frame is unmodified.

43.5.1.3.5 Mode 4 — Double Tagging with Replace

Insert tag on untagged and single-tagged frames. If a double-tagged frame is received, overwrite the outer tag.

43.5.2 IP Snooping

The switch supports programmable snooping for up to eight programmable IP protocols. If the protocol field of an IPv4 or IPv6 frame matches one of the programmed values and snooping is enabled for that entry, the frame can be processed as follows:

- Forward to designated management port only
- Copy to management port and normal forward/flood
- Discard on match

The management port is identified by the port number set in the ESW_BMPC register. The function is configured using ESW_IPSNP1–8.

The snooping function can be enabled/disabled individually for each of the entries. If no protocol matches, a match occurs but snooping is disabled, or the frame is coming from the management port itself, the frame is processed normally.

Note

Snooping respects any optional VLAN tags (i.e. extracts next after last VLAN tag).

43.5.3 TCP/UDP Port Number Snooping

Programmable snooping for up to eight programmable TCP or UDP port numbers. If the source or destination port number field within an TCP/IP or UDP/IP frame (IPv4 and IPv6) matches the compare value and snooping is enabled for that entry, the frame can be processed as follows:

- Forward to designated management port only
- Copy to management port and normal forward/flood
- Discard on match

The management port is identified by the port number set in the ESW_BMPC register. The function is configured using ESW_IPSNP1–8.

The snooping function can be enabled/disabled individually for each of the entries. If no entry matches, a match occurs but snooping is disabled, or the frame is coming from the management port itself, the frame is processed normally.

Note

Port number snooping is possible only if the IP header ends up to ten words (40 bytes) after the MAC header. If the IP header ends later (e.g. IPv6 + VLAN or IPv4 + >20 byte options) the port numbers cannot be parsed any more and the port number snooping is ignored (protocol-based snooping is not affected by this limit).

For IPv6 frames the port number can only be compared if the UDP or TCP header is the very next header to the IPv6 header (i.e. it does not detect such headers if any extension headers are present in an IPv6 frame before the TCP or UDP header).

43.5.4 VLAN Output Processing Function

The VLAN output processing function is used on a switch output port to manipulate the VLAN tag of the outgoing frames that leave the switch. Frames are processed based on the output processing mode and the number of tags in the frame.

43.5.4.1 Configuration Information

The switch management provides the information on operating mode to configure and control the operation of the function using the ESW_VOMSEL register of a port. There are three different modes of operation, which define how the outgoing frames should be processed.

43.5.4.1.1 Mode 0 — Disabled

No frame manipulation occurs.

43.5.4.1.2 Mode 1 — Strip Mode

In strip mode, all the tags (single or double) are removed from incoming frame.

43.5.4.1.3 Mode 2 — Tag Through Mode

In tag through mode, the inner tag is passed through while the outer tag is removed for a double-tagged frame. The following rules apply:

- When a single-tagged frame is received, strip the tag from the frame.
- When a double-tagged frame is received, strip the outer tag from the frame.

43.5.4.1.4 Mode 3 — Transparent Mode

In transparent mode, a single-tagged frame is unchanged. The following rules apply:

- When a single-tagged frame is received, frame is unchanged.
- When a double-tagged frame is received, strip the outer tag from the frame.

43.5.5 Frame Classification and Priority Resolution

When a frame is received on an input port, several pieces are extracted from the frame (Ethernet MAC address, VLAN tag, and IP headers) to determine the frame type and perform the relevant classification actions.

In addition, the MAC address table can provide a priority indication for the destination MAC address if the switch management has programmed the address table accordingly (static entry).

The frame is classified in up to four priority levels (0 = lowest, 3 = highest) and is eventually queued in the corresponding priority queue at the output port.

43.5.5.1 VLAN Priority Look-Up

An eight-entry programmable priority table is implemented on each port. The ESW_P*n*VRES registers contain the priority mapping for port *n*.

The switch uses 3-bit priority field from the VLAN tag information to extract the corresponding bits from the table, which indicates which priority the frame is finally classified.

The index in the mapping table is the three bits of the first octet of the VLAN tag data (bit 5 (prio0) is the lsb and bit 7 (prio2) is the msb).

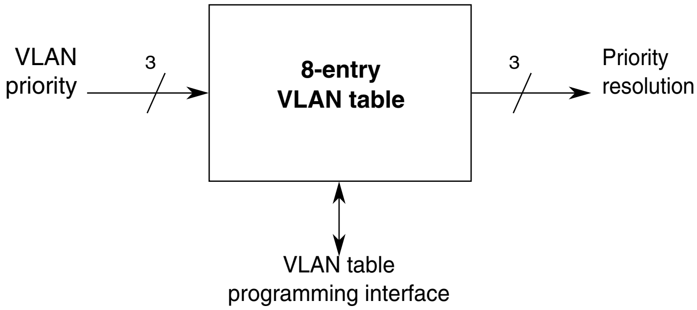

Figure 43-123. VLAN Table Overview

43.5.5.2 IPv4 and IPv6 Priority Look Up

The switch can classify IPv4 and IPv6 frames:

- A 64-entry table is implemented per port to classify the IPv4 frames
  - The frame's six-bit DiffServ field is provided and the table returns the 3-bit priority information
- A 256-entry table is implemented per port to classify IPv6 Frames (IP COS tables)
  - The eight-bit class of service field is provided and the table returns the 3-bit priority information

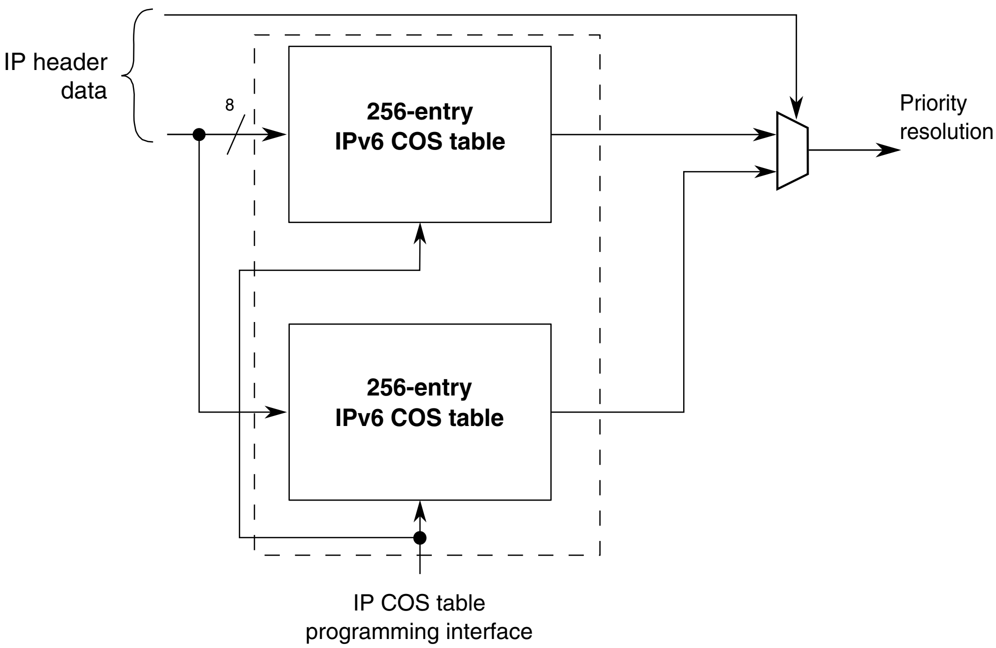

Figure 43-124. IP COS Tables Overview

43.5.5.2.1 Classification Table Programming Model

An indirect addressing scheme is implemented to program the mapping tables using a single register (ESW_IPRES).

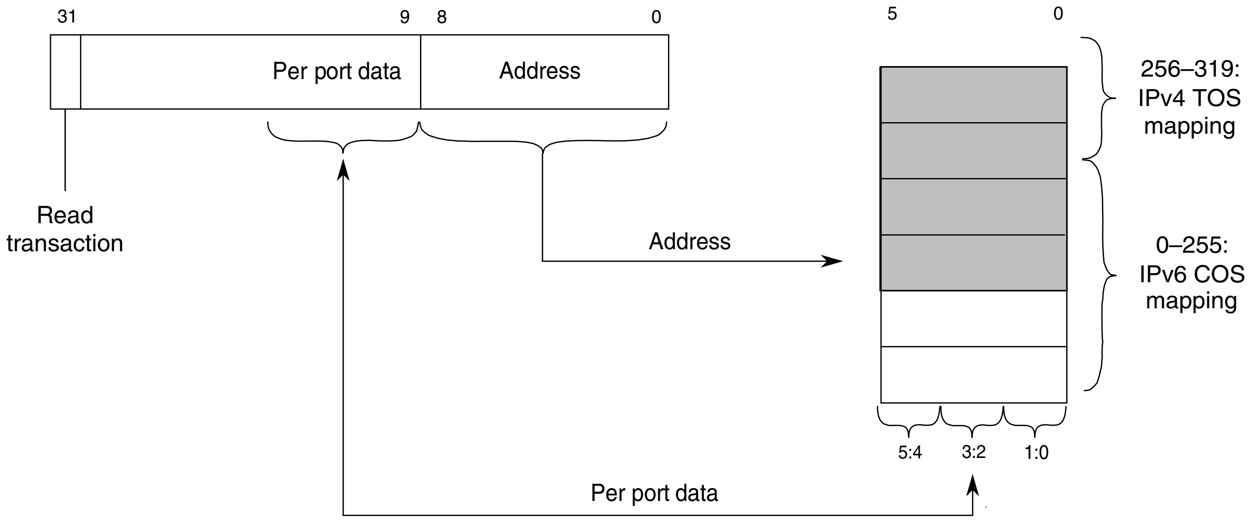

Figure 43-125. ESW_IPRES Mapping Table Programming Model

The table is implemented in a single 320-deep table used for IPv4 6-bit TOS and IPv6 8-bit COS mappings.

- The first 256 entries represent the IPv6 COS field mapping. The received COS field of a frame is used to address a row from 0–255. The value stored is read and used as priority for the frame.
- The last 64 entries represent the IPv4 DiffServ field mapping. The received DiffServ (upper 6-bits of TOS) value of a frame is used to address a row from 256–319.
- Each entry of the table provides the priority mapping in bits 1:0 for port 0 (00 = queue0, 01 = queue1, 10 = queue2, 11 = queue3), bits 3:2 for port 1, and bits 5:4 for port 2.

To write a table row into the table the address is provided in bits 8:0 and the data in bits 13:9, where bit 9 represents bit 0 of the data and bit 13 represents bit 5 of the data.

To read a table row, the read bit must be set when writing into the ESW_IPRES register. This triggers a read transaction to the address provided in bits 8:0 of the register. After this, reading the register provides the data returned from the table for this address.

When writing an entry into the table, software can only write the mapping for all ports in one write transaction. Therefore software must implement a read-modify-write scheme, to:

1. Read the current table contents
2. Modify the priority bits for the port of interest without modifying the other ports bits
3. Write back the complete data word into the table

43.5.5.3 Priority Resolution

The priority resolution function is independently programmable on each port through the ESW_P*n*RES registers by enabling or disabling VLAN, IP, or MAC address-based classification (see Port 0 priority resolution configuration (ESW_P0RES)).

The priority resolution follows the following rule set depending on which classifications are enabled (ESW_P*n*RES) and which fields are found within the frame:

- If IP classification is enabled and an IP header found, map the priority according to the ESW_IPRES table
- Else, if VLAN classification is enabled and a VLAN tag is found, map the priority according to the ESW_P*n*VRES table
- Else, if MAC classification is enabled and MAC address found, take the priority from address table, if it is a static entry
- Else, use default priority as specified in ESW_P*n*RES

43.5.5.4 Bridge Control Protocol Identification

To allow for implementation of bridge control protocols like the spanning tree protocol, all control frames (bridge protocol data units, BPDU) are marked when they enter the switch. The mark then can be used by the input port blocking function to drop the frame after the address learning (see Protocol Snooping).

In addition, the function can be configured to pass all frames or to pass only control frames (e.g. covering spanning tree port states blocking, listening, and learning) and discard all other frames.

43.5.6 Input Port Selection

The port selection constantly polls all input ports for available data. If any data is available, the port is selected and frame data is read from the input. After one frame is read, another port is selected, even if more data is available on the current port.

This means for the application on a port atlantic input interface, that it is not allowed to perform back-to-back frame transfers to the switch. Instead the application must wait for a new selection after one frame has been transferred.

43.5.7 Layer 2 Look-Up Engine

A hash code is calculated using the frame destination's MAC address. It is used as an entry (address) to a table, which contains MAC addresses with destination port number and validity information.

As one hash code value can represent more than one MAC address, the memory implements for each pointer, up to eight MAC address entries, which are searched linearly.

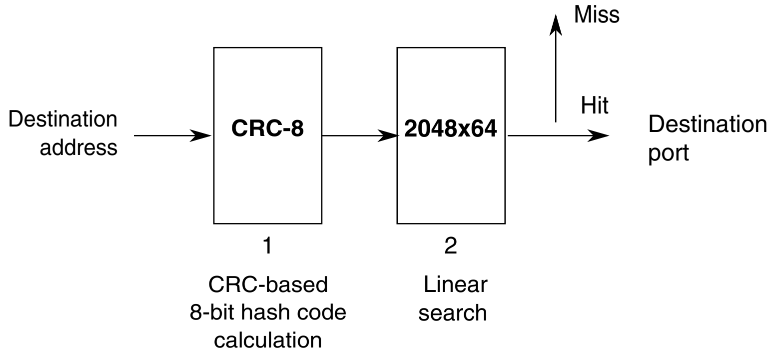

Figure 43-126. Port Look-Up Overview

43.5.7.1 Hash Code

For a MAC address table up to 2048 entries, an 8-bit hash value is calculated from the 48-bit destination MAC address. The hash code uses a CRC-8:

$x^8 + x^2 + x + 1$ (0x07)

43.5.7.2 Address Memory

The address memory is divided into blocks. Each block contains eight records, which contain 64 bits of information each. Each record contains the 48-bit MAC address and provides the necessary forwarding information, and priority or timestamp information.

Two types of records are defined:

- Dynamic record — The dynamic entry provides the MAC address together with a 10-bit timestamp and destination port number. These entries are created by the learning function based on received frames to enable forwarding of frames to dedicated ports. Dynamic entries are deleted by the aging function if not updated.
- Static multiport/priority record — Switch management can also write static entries in the table, which can include priority information and multiple destination ports for forwarding. The MAC address can be unicast or multicast. These records can be used to specify the ports to participate in a specific multicast domain or to assign a MAC address based priority to a frame. The aging and learning functions ignore static records.

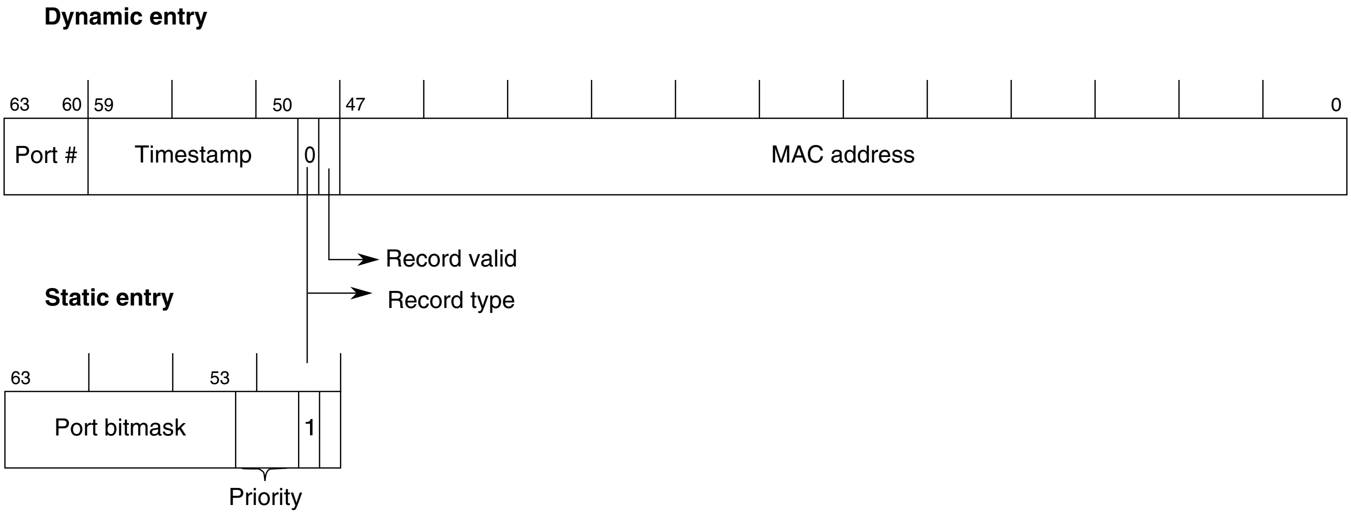

Figure 43-127. Address Memory Record Types

The record's bit 49 decides which type of record is found in the table:

- If 0, a dynamic entry is available. The 10-bit timestamp and 4-bit port number are given in the upper bits of the record.
- If 1, a static entry is available with a 3-bit priority field followed by a 3-bit port bit mask. The record bit 53 represents port 0, bit 54 port 1, and bit 55 port 2. The frame is forwarded to all ports whose port bitmask is set. The source port is removed dynamically from the bitmask during forwarding (a frame is never forwarded to the port where it came from).

The 48-bit MAC address is stored with the first octet in bits 7:0 and the sixth octet in 47:40 of the record.

43.5.8 Layer 2 Lookup Tasks Overview

43.5.8.1 MAC Address Lookup

The 48-bit destination MAC address of each frame received by the switch, on any of its interfaces, is extracted by the hardware and provided to the look-up engine together with the physical interface number. If the frame carries a VLAN tag, the tag information is also extracted and provided to the look-up engine.

If the received frame is a unicast or multicast frame, a two-stage lookup process is implemented. The look-up engine first calculates the hash value from the MAC address. The hash code is used as an entry to the switch address table. The look-up function can provide three results with tree different associated actions performed by the switch hardware:

1. The address is in the table and associated with a correct port number:

   The switch forwards the frame only to the looked up port.

2. The address is in the table but is associated with the port on which it was received:

   The switch discards the frame and does not forward it to any port.

3. The address is not found in the table:

   The switch engine sends the received frame to all ports except the port on which it was received (flooding).

If a broadcast frame is received, the switch hardware sends the received frame to all output ports, except the one from which it was received (flooding).

Note

Flooding and additional frame filtering can be controlled (for example, to avoid the duplication of critical information to unwanted destinations) with the mechanism described in Broadcast/Multicast/VLAN Domain Resolution.

43.5.8.2 Forced Forwarding

The MAC address lookup result can be overwritten using the forced forwarding configuration available in the ESW_FFEN register. This feature is available only for frames coming from the local port (port 0).

When forced forwarding is enabled for a frame, the frame is forwarded to the forced destination ports, ignoring any results from the MAC destination address lookup. Forced forwarding only replaces the MAC lookup function, all other filtering functions (e.g. VLAN verification) act as normal.

43.5.8.3 Learning

The switch hardware extracts the source MAC address of each frame received on each of the switch ports and provides it (via the ESW_LREC0 and ESW_LREC1 registers) to the switch firmware which implements the learning task. The ESW_LSR register indicates availability of learning data.

43.5.8.3.1 Learning Interface

The interface implements a FIFO buffer that stores up to 32 words of 32-bit each.

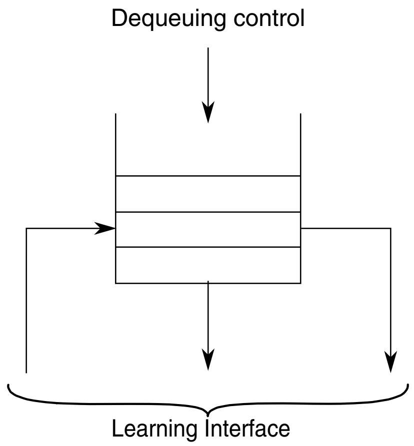

Figure 43-128. Learning Interface Overview

For each frame processed by the switch engine, two 32-bit records (record A0 and record B1) are written in the information FIFO. Record A is written first.

The MAC address available in records A0 and B1 is the source MAC address of the frame. Record A holds the first four bytes of the frame source address, and record B contains the last two bytes.

The hash code in record B is calculated with the source MAC address and the same hash polynomial used for look-up, as defined in Hash Code.

The 4-bit port number defines the port/MAC address association.

Table 43-123. Frame Information Records — 8-Bit Hash Values

	3 3 2 2	2 2 2 2	2 2 2 2	1 1 1 1	1 1 1 1	1 1		
	1 0 9 8	7 6 5 4	3 2 1 0	9 8 7 6	5 4 3 2	1 0 9 8	7 6 5 4	3 2 1 0
Frame record A	MAC address							
Frame record B	Reserved	Port #	Hash code		MAC address (cont'd)			

When information for at least one frame (two records) is available, the status indication in ESW_LSR register is set. To read the frame records, read the ESW_LREC0 register (record A) first followed by the ESW_LREC1 register (record B).

Note

Reading ESW_LREC1 triggers the retrieval of the next record pair from the FIFO, if any.

The learning task (software) uses this information and then executes as follows:

1. For every frame received, the source address with port and timestamp information is stored in the address lookup table. The following information is stored for each entry:
   - MAC address
   - Time stamp: a 10-bit value, determines the age of an entry
   - Port number: a 4-bit value, indicates the port the frame was received
2. If the MAC address table is full, a new entry replaces the oldest entry with an identical matching hash value.

43.5.8.4 Migration

If the firmware receives a MAC address, which is already in the switch table but is associated to a different physical port number, the current entry is overwritten with the new information and the timestamp is set to the current time.

43.5.8.5 Aging

Aging refers to deleting old entries within the table. It proceeds as follows:

1. The 10-bit timestamp is stored with all the entries and is updated each time the source address appears.

2. If a record is not updated for a longer period of time, it is removed from the table if it is a dynamic entry.
3. Static entries are not affected by the aging process and are always kept.

This process runs continuously in the background of the firmware. The aging period is software-controlled and programmable, defaulting to four seconds per step. This gives a range of 4 seconds to 68 minutes.

43.5.9 Frame-Forwarding Tasks

When an input port is selected the frame is forwarded to its corresponding output port. Output port resolution and switching is based on the information from the two-stage MAC address look-up (see Layer 2 Lookup Tasks Overview) followed by additional resolution functions to allow frame duplication and flooding control. These are described in the following sections.

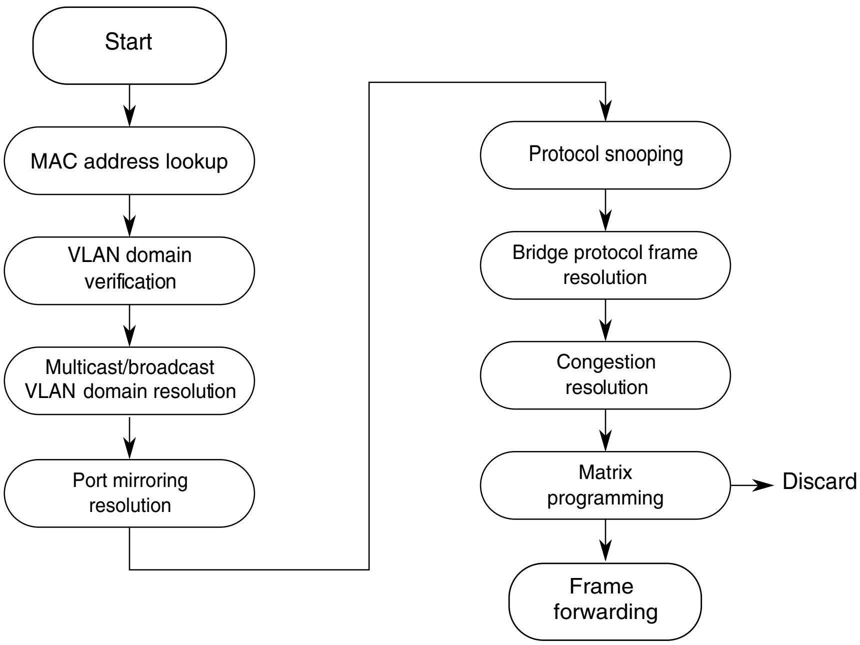

Figure 43-129. Frame Forwarding Tasks Overview

43.5.9.1 VLAN Domain Verification

When the L2 MAC address lookup is successful and identifies a dedicated output port for the frame, the output and input port can be verified to be in the correct VLAN domain if VLAN verification is enabled for the port and the frame contains a VLAN tag. The VLAN resolution table (see VLAN Resolution Table) is used as follows:

- If the frame's VLAN ID is in the table but the output port number is not a member of the VLAN domain, or the input port is not a member of the VLAN domain, the frame is marked invalid and is eventually discarded.
- If the frame's VLAN ID is in the table and the output and input ports are members of the VLAN domain, the frame is forwarded normally.
- If the frame's VLAN ID is not found in the VLAN table or the frame has no VLAN tag, the frame is forwarded normally (default broadcast domain), or if the discard bit for the port is set (also in register ESW_VLANV) it is discarded.

43.5.9.2 Broadcast/Multicast/VLAN Domain Resolution

To ensure that traffic within VLAN channels are always routed to the correct ports, for example to avoid the duplication of critical information through a network, the switch implements a resolution mechanism that, for any frame that is switched to multiple ports, checks the VLAN ID provided with the current frame.

The VLAN resolution mechanism searches the VLAN resolution table (see ESW_VRES*n* registers), which stores up to 32 unique VLAN IDs, each associated to a port bit mask. The resolution mechanism is used for the following conditions:

- Unicast frames with a destination MAC address that are not in the table of the layer 2 engine
- Multicast frames with a destination MAC address that are not in the table of the layer 2 engine
- Any broadcast frame

43.5.9.2.1 VLAN Resolution Table

The VLAN resolution table (ESW_VRES*n*) provides a unique VLAN ID/port bit mask association for up to 32 VLANs. A default entry (ESW_DBCR) provides an additional port bit mask. The port bit mask implements one bit for each port.

Each port bit indicates, if set, that it is member of the VLAN and frames with the corresponding VLAN ID can be switched to the port. If the port bit is cleared, a frame with the corresponding VLAN ID is not switched to that port. If no VLAN ID matches, the default mask is applied.

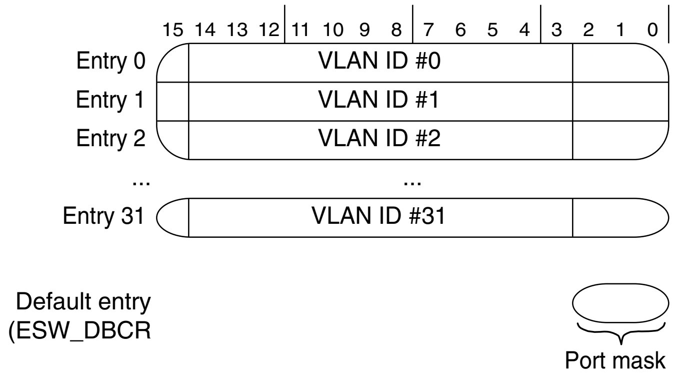

Figure 43-130. VLAN Resolution Table Overview

43.5.9.2.2 VLAN Switching / Resolution Mechanism

The VLAN table is used for VLAN domain verification (see VLAN Domain Verification) and VLAN resolution. Once the frame has passed any VLAN domain verification (i.e. will not be discarded by the verification function already) the forwarding resolution applies.

- If the destination MAC address (Unicast or Multicast) is found in the MAC address table and
  - the frame carries a VLAN tag that is found in the VLAN table, the frame can be forwarded only to the ports within the VLAN domain and will be discarded if the destination port is not member of the VLAN domain.
  - else if the frame carries a VLAN tag that is not found in the VLAN table, or does not contain a VLAN tag, it is forwarded as indicated by the lookup table (note that VLAN domain verification can be configured to discard the frame in this case if enabled).
- If the destination MAC address (Unicast or Multicast) is not found in the MAC address table, or if the destination address is the Broadcast address, the frame is forwarded according to the following rules:
  - If the frame carries a VLAN tag, the VLAN resolution table is searched for a matching VLAN ID and the frame is sent to all ports that are associated with the VLAN ID.
  - If the frame carries a VLAN tag and the VLAN ID does not match any entry in the VLAN Resolution Table, the frame is forwarded to all ports that are enabled to receive broadcast frames by the default entry.

- If the frame does not carry a VLAN tag the frame is forwarded to all ports that are enabled to receive broadcast frames by the default entry.
- The frame is discarded, if it cannot be associated with any VLAN group and if the default (broadcast) group has been set to all zero.

To disable the VLAN resolution set all VLAN IDs to 0xFFF or (0x000 if that ID is not used) and all port mask bits to 1. If the VLAN resolution is disabled, normal port flooding is implemented as described in Frame Classification and Priority Resolution. The default entry can still be used to restrict broadcast to only dedicated ports, if not programmed to all 1s.

43.5.9.3 Port Mirroring

The function allows duplicating traffic to a dedicated mirror port. Any one of the ports can be assigned to act as a mirror port (register ESW_MCR).

The mirror port then is always added to the list of output ports and therefore receives a copy of the frame, if any of the following rules matches with the currently processed frame:

- Ingress Port Number Match

  When a frame is received on port N and the corresponding bit in the register ESW_INGMAP is set to 1, the frame is mirrored.
- Egress Port Number Match

  When a frame is forwarded to port N and the corresponding bit in the register ESW_EGMAP is set to 1, the frame will be mirrored.
- MAC Ingress SA Match

  When the Ingress Port Number match succeeded (see above) and the MAC source address matches the ESW_INGSA{L,H}, the frame will be mirrored.
- MAC Ingress DA Match

  When the Ingress Port Number match succeeded (see above) and the MAC destination address matches the ESW_INGDA{L,H}, the frame will be mirrored.
- MAC Egress SA Match

  When the Egress Port Number match succeeded (see above) and the MAC source address matches the ESW_EGSA{L,H}, the frame will be mirrored.
- MAC Egress DA Match

When the Egress Port Number match succeeded (see above) and the MAC destination address matches the ESW_EGDA{L,H}, the frame will be mirrored.

In addition, a counter is implemented (Register MIRROR_COUNT) that allows specifying that only every Nth frame that matches any of the above criteria is mirrored. If the counter is set to 1 or 0, every frame is mirrored that matches any of the above criteria.

43.5.9.4 Protocol Snooping

The incoming frames are parsed for IPv4 and IPv6 headers and UDP/TCP if available. The snooping function can be programmed to redirect specific protocols exclusively to the management port. See IP Snooping and TCP/UDP Port Number Snooping for a description of the snooping options.

The snooping is active only for frames received from the external ports. When a frame is transmitted from the management port itself, snooping does not apply and the frames are forwarded normally (MAC lookup).

43.5.9.5 Bridge Protocol Frame Resolution

To implement bridge control protocols like the Spanning Tree protocol, the following control functions are performed by the Protocol Frame Resolution function:

43.5.9.5.1 Input Port Blocking

The input port blocking function is used to avoid forwarding of frames after address learning. The firmware can program the ESW_BKLR register and if a frame is received on port *n* that should be blocked (BE*n* = 1) and the frame is not a bridge protocol frame (see below), the frame is marked for discard and is not forwarded to any output port.

43.5.9.5.2 Input Port Learning Disable

To reduce processing load from the firmware, a port can be configured for exclusion from learning (see the ESW_BKLR register).

When learning is disabled on a port no source address extraction happens for incoming frames, with the exception of incoming BPDU frames. BPDU frame source addresses are always extracted and forwarded to the learning interface.

43.5.9.5.3 Management Port Forwarding

If enabled, bridge protocol frames are always forwarded to the dedicated management port (see the ESW_BMPC register) independent of any address lookup or other resolution functions.

Bridge protocol frames are identified by its destination address being any of the following:

- 01-80-C2-00-00-00 to 01-80-C2-00-00-0F (Spanning Tree, IEEE 802.1d, Table 7-9)
- 01-80-C2-00-00-10 (Bridge Management Address, 802.1d, Table 7-10)
- 01-80-C2-00-00-20 to 01-80-C2-00-00-2F (Generic Attribute Registration Protocol, 802.1d, Table 12-1)

43.5.9.5.4 Management Frame Forwarding

If the management port transmits Frames, they are forwarded according to the port mask defined in the configuration register ESW_BMPC. A handshaking mechanism is implemented that can be used by the firmware to configure the destination port mask on a frame-by-frame basis for management frames.

Note: VLAN domain verification/discard (see the ESW_VLANV register) should be switched off for the management port to avoid that the switch discards management frames.

43.5.9.6 Congestion Resolution

The congestion resolution function is used whenever an output port is not available and data needs to be sent to that port. An output port is defined to be available if the port is enabled (bit in ESW_PER set 1) and the output buffer (shared memory) is not congested. If, for a port, one of these conditions is not valid, the port is not available and frames cannot be switched to that port.

The congestion resolution function determines whether the frame should be processed further or discarded according to the following rules:

43.5.9.6.1 Unique Destination (one input to one output)

If the output port is enabled and can accept a frame the frame will be forwarded normally.

In any other case the frame will be discarded. If a frame switched to port N, the counter ESW_P*n*OQC is incremented.

43.5.9.6.2 Multiple Destinations (Flooding)

After broadcast / flooding resolution a frame needs to be switched to multiple output ports.

- Output disabled: All disabled ports are removed from the list of outputs.
- Output congestion: If any of the outputs cannot accept a frame (As indicated by the output queue management for the port, implementation specific) it is also removed from the list of outputs.

If no output port is left in the list of outputs, the frame is discarded.

If a frame switched to port N, the counter ESW_P*n*OQC is incremented.

43.5.9.7 Switching

After the output port(s) have been determined, the switch control enables the corresponding path though the Switch Matrix and the frame is forwarded to the output queue(s).

In a similar fashion, if a Frame should be switched to multiple ports (e.g. Broadcast), the switch control enables the corresponding paths though the Switch Matrix and the frame is forwarded to all the destination output ports.

43.5.10 Output Frame Queuing

The memory controller implements a shared memory architecture to store Frames of arbitrary size for multiple destination ports.

Each destination port implements 4 priority queues. The memory controller implements a single write input port and three output ports with the capability to perform virtual frame duplication on the output ports (Multiple reads on multiple ports of a single frame stored in the buffer).

A single large memory, partitioned in 256 byte cells, is implemented to efficiently share the available space for small and large frames without leaving large unused spaces when storing small frames.

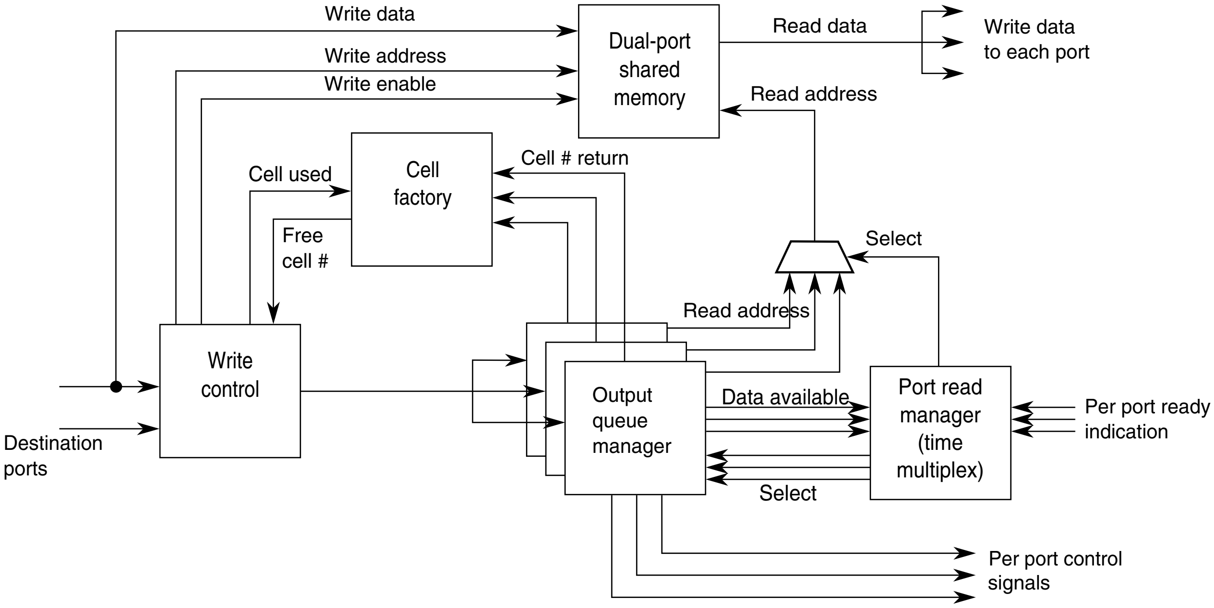

Figure 43-131. Memory Controller Overview

43.5.10.1 Cell and Queue Concept

The shared memory is partitioned in 256 byte cells using a 32-bit datapath implementation. This results in a cell holding 64 32-bit words.

Incoming frames are stored, partitioned in cells, in the shared memory and only the cell numbers are managed by the individual port queues.

Due to the arbitrary length of incoming frames, the last cell may not be fully utilized. A frame can spread from one to any number of cells. The number of bytes used in the last cell is also stored in the queue FIFO together with the individual cell numbers.

Cells can be stored anywhere in the shared memory. A single frame must not necessarily be stored in consecutive cells but instead can be scattered over the complete memory at arbitrary positions. The start of a cell is fixed to a 64-word boundary (i.e. the memory start address of a cell is simply the cell # multiplied by 64).

Per port, a queue FIFO is implemented that stores the cell numbers for the frames The number of bytes used in the last cell is also stored in the queue FIFO together with the individual cell numbers.

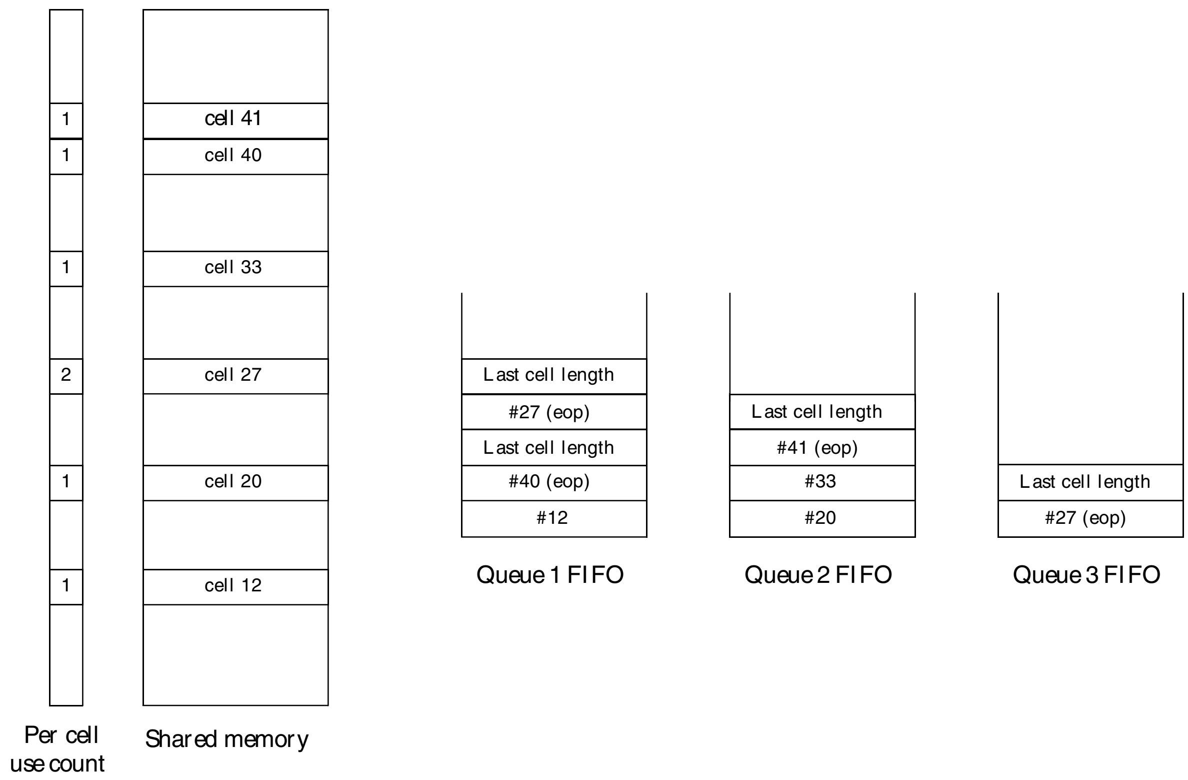

Figure 43-132. Cell storage concept

The example in the figure above shows the storage of three frames with one frame duplicated and stored in two queues.

43.5.10.2 Write Control Module

The Write Control Module receives frames from the Switch engine, partitions and stores the frames in the shared memory. The cell numbers used to store the frame are forwarded to the port output managers.

43.5.10.3 Cell Factory Module

The Cell Factory implements the cell management, it always provides a free cell number to the write control module so the write control module can immediately start writing into memory to avoid any write latency.

43.5.10.4 Output Queue Manager

The Output Queue Manager implements, per port, the individual queue FIFOs (One queue FIFO per priority). The queue FIFOs are addressed by the priority information extracted by the Switch classification engine. Per port, eight prioritized queues are implemented.

When more than one queue has data available, the read logic selects one of the queues with a Weighted Fair Queuing scheduling algorithm.

43.5.10.4.1 Weighted Fair Queuing Scheduling Algorithm

The weight of each queue, common for all ports, can be configured between 0 and 30 with the register ESW_QWT. A Queue with a higher weight is served more often than a queue with lower weight.

Queue 0 represents the lowest priority, Queue 3 the highest priority queue.

The scheduler first serves the queue with the highest weight. Each time the scheduler serves a queue, the weight of the other queues is increased and the weight of the selected queue is reset (decreased) to its programmed weight value. This guarantees that all queues are served eventually.

When multiple queues have the same weight the queue with the higher number is served first.

If all weights are programmed to 0 (default) a strict priority scheme is active where the higher priority queues are served as long as they are not empty.

43.5.10.5 Congestion Management

The Write control logic is protected against memory overflow. When data is written is the cell factory has no more free cells (Number of available cells less than value programmed in register ESW_LMT), the frame is discarded or terminated with an error (i.e. forwarded to the output queue manager with the end-of-packet and error indication).

If the congestion persists, the switch resolves the congestion as specifies in Congestion Resolution.

43.5.11 Reset and stop functions

43.5.11.1 Stop Controls

The register ESW_MODE offers several bits that control output pins. In addition some controls have an effect on internal logic functions:

- stop_en: no internal function.
- switch_en: when de-asserted, all DMA registers are cleared.
- switch_reset: no internal function.

An external logic may use the controls to disable or enable the switch function as necessary.

43.5.11.2 Port Disable

The switch toplevel offers a disable input for each port (port_dis(2:0). When a pin is asserted (1), the corresponding port enable bits within register ESW_PER for both transmit and receive will be cleared.

This results in the following behavior:

- If the port-enable bits of port0 are cleared, it also resets the input buffer and output buffer at the port0 DMA interface.
  - The ready output to DMA0 will be asserted allowing the application to continue writing data at the interface, which will be ignored (application flush). No further transmitted frame status will be given (i.e. for any currently stored if any, as well as the currently ignored).
  - If the transmit enable is cleared while the interface is currently transferring a frame to the DMA, the frame is aborted (output buffer reset). The eop is not produced. Therefore the connected DMA module must be reset to ensure proper restart after re-enabling the port.
- If any port's transmit enable bit is cleared, the shared memory will continue delivering the frames stored currently for a port as normal (i.e. flushing the memory). New frames will be discarded before they are written into the shared memory. That is, no invalid frame will appear on the MAC interfaces after disabling or re-enabling a port.
- If any port's receive enable bit is cleared while a frame is transferred, this frame will be aborted with an error internally. The port's ready indication will stay asserted to flush any application data. Reenabling the port at any time will ignore any input data until a sop starts a new frame.

43.5.11.3 Port 0 Input Protection

The port 0 input buffer is protected for application errors that abort a frame without writing a proper eop to the interface. The next frame then written to the port 0 transmit interface will be concatenated with whatever data was already written before, but the frame will be marked with an error and hence will be forwarded and transmitted with an error indication (mii tx error).

If the port0 input buffer is reset (by deasserting ESW_PER receive enable bit) while a frame is transferred to the switch internally, the frame transfer will be aborted in a clean way (producing an eop with error indication) to avoid blocking the switch.

43.5.11.4 Port 1/2 Input Protection

Ports 1 and 2 are protected for a 2nd SOP in case the MAC is reset in the middle of a receive transaction to the switch hence did not produce a proper EOP to the switch. The next frame will be concatenated with whatever was provided to the switch before and marked with an error.

If the MAC is stopped in the middle of a transaction, the switch is blocked, waiting for the EOP, not serving any of the other ports. Clearing the ESW_PER receive enable bit in this situation will terminate the frame with an error internally to the switch hence remove the blocking condition.

43.5.11.5 DMA Bus Error

When the DMA bus error input (dma_eberr_int) is asserted, the DMA registers are all cleared. If the corresponding interrupt was enabled the ipi_eberr_int pin will be asserted.

Chapter 44
Universal Serial Bus (USB) Controller

44.1 Overview

The USB controller block provides high performance USB functionality that complies with the USB 2.0 specification. It is a dual role device which can be configured to act as Host or Device through firmware interface. It is not a true OTG controller.

The USB controller consists of two independent dual role(host/device) USB controller cores. Each controller core has a UTMI interface and is connected to on-chip PHY. For a detailed description about the features, please refer to Features. It is used as both a downstream and upstream port.

The following figure is a block diagram of USB.

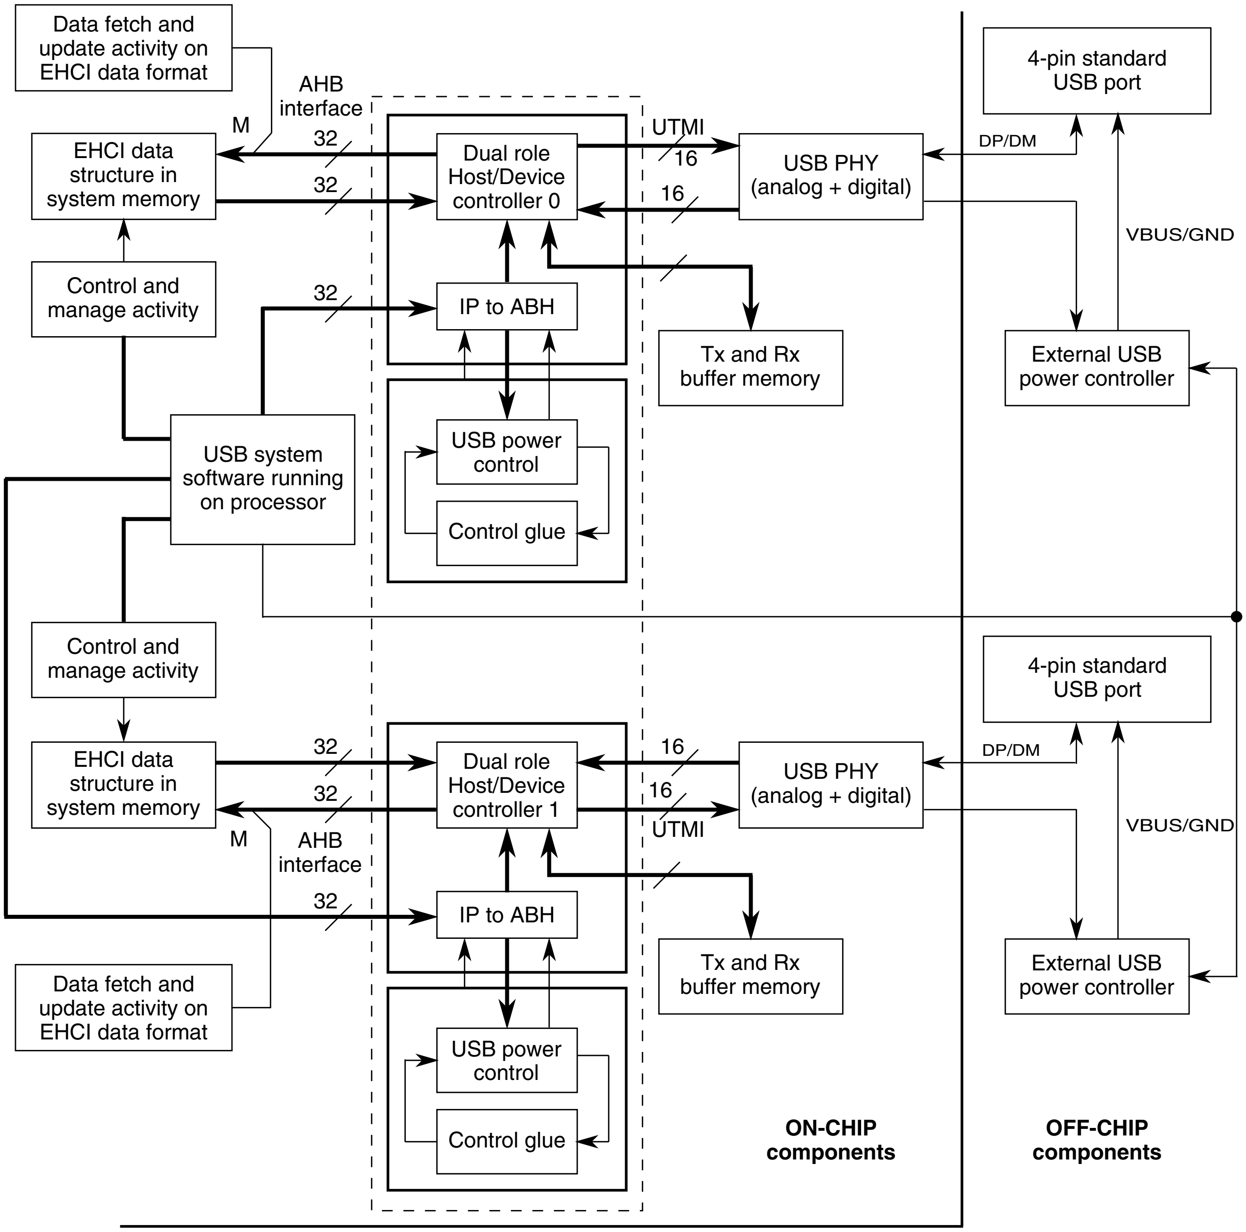

Figure 44-1. USB block diagram

44.2 Features

The USB includes the following features:

- High-speed dual role Host/device controller core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in Host mode
  - High Speed, and Full Speed operation in Peripheral mode
  - Up to six bidirectional software configurable endpoints

- Low-power mode with local and remote wake-up capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
- Embedded DMA controller.

44.2.1 Ports

These are detailed list of Ports on each USB devices on Vybrid:

- USB_DCAP — Common for both of the controller. Connected are two 1.1 pf cap on them.
- USB0_DM — Connect directly to USB four pin connectors DM pin.
- USB0_DP — Connect directly to USB four pin connectors DP pin.
- USB0_GND — Connect directly to USB four pin connectors GND pin also, connect it to ground of board.
- USB0_VBUS — Connect to external power controller.

If USB is configured as:

- Self powered device — The external power controller will drive it with 5 V supply.
- Bus powered device — The external power controller will connect it to VBUS of cable.
- Host, connected to bus powered low power device then external power controller will drive 100 mA of current to VBUS of cable.
- Host, connected to bus powered high power device then external power controller will drive 500 mA of current to VBUS of cable.

If the consumed current is exceeding the rated current then the external power controller will report Vybrid on USBx_VBUS_OC and in that case, Vybrid USB will suspend the port.

- USB0_VBUS_DETECT — Connected to cable VBUS in case of any mode. External power controller need to drive this on detection of cable connected.
- USB0_VBUS_EN — Will be connected to external power controller. This indicates to enable the VBUS supply.
- USB0_VBUS_OC — Indicated by external power controller about connected device is fetching more current than the configured one.
- USB0_SOF_PULSE — Can be used to configure sample rate to any of external audio/video sampler to match rate with current USB bus speed.

44.2.1.1 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode. Each USB controller core can be configured for High Speed operation (480 Mbps), Full Speed operation (12Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

44.2.1.2 Normal Mode

The USB controller can be configured to work in either Host mode or Device (Peripheral mode).

The USB is not a true OTG. It can be configured by software to function either as peripheral or as host. The ID pin, which is unique for OTG operation, is not present in this implementation. There are no five pin interface. The user will get four pin host/ device interface.

44.2.1.3 Low Power Mode

Each USB PHY has a low power mode (Low power Suspend Mode) to reduce power consumption. It can be entered by setting bit "PHCD" in USB_PORTSC1 register. This bit must only be set after the bus is in suspend state. When operating as host, software can set the SUSP bit in the PORTC1 register to suspend the bus. When operating in peripheral mode, the controller will automatically enter suspend mode when the bus has been idle for 3 ms. At that time, software can enable the low-power suspend feature in the PHY.

Either the local ARM platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For detail about Suspend/Resume, please see USB Power Control Block.

44.3 Non-core Registers

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers. These registers are implementation specific. The registers and the bit mapping may vary across different devices.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer toRegister Interface.

NOTE

For reserved bits, please preserve the value when writing (read its reset value, then write this value back).

"USB" prefix in register name indicates it is a core register for USB controller core.

"USBC" prefix in register name indicates it is a USB non-core register.

USBC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_5800	USB Control Register (USBC0_CTRL)	32	R/W	0000_3000h	44.3.1/2144
4003_5818	UTMI PHY Control Register (USBC0_PHY)	32	R/W	0000_0000h	44.3.2/2147
400B_5800	USB Control Register (USBC1_CTRL)	32	R/W	0000_3000h	44.3.1/2144
400B_5818	UTMI PHY Control Register (USBC1_PHY)	32	R/W	0000_0000h	44.3.2/2147

44.3.1 USB Control Register (USBCx_CTRL)

The USB control register controls features that are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: Base address + 800h offset

USBCx_CTRL field descriptions

Field	Description
31 WIR	USB Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the USB port. This bit is cleared by disabling the wake-up interrupt (clearing bit "WIE"). 1 Wake-up Interrupt Request received 0 No wake-up interrupt request received

Table continues on the next page...

USBCx_CTRL field descriptions (continued)

Field	Description
30–26 Reserved	This field is reserved.
25 VBUS_CH_INT_ MASK	When this bit is set, generation of VBUS_EN_INTR is masked. 0 VBUS_EN_INTR not masked 1 VBUS_EN_INTR masked
24 VBUS_CH_STAT	This bit is set by host controller whenever Port Power Enable/Disable event occurs. 0 No Change in Port Power 1 Change in Port Power Control
23–18 Reserved	This field is reserved.
17 WKUP_VBUS_ EN	Wake-up on VBUS change enable 1 Enable 0 Disable
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 WKUP_SW	USB Core Software Wake-up 1 Force wake-up 0 Inactive
14 WKUP_SW_EN	USB Core Software Wake-up Enable 1 Enable 0 Disable
13 UTMI_ON_ CLOCK	Force USB Core UTMI PHY clock output on even if suspend mode. 1 Force clock output on 0 Inactive
12 SUSPENDM	Force OTG UTMI PHY Suspend This bit is used to force PHY into low-power mode. During normal operation, software should set bit PHCD, after the bus is suspended, in USB core register PORTSC1 to put PHY into low-power mode. For Freescale test only. 1 Inactive 0 Force OTG UTMI PHY Suspend
11 RESET	Force USB UTMI PHY Reset Not for use in normal operation. During normal operation, software should set USBCMD. RST bit to reset the UTMI PHY 1 Reset the PHY 0 Inactive
10 WIE	Wake-up Interrupt Enable This bit enables or disables the wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode

Table continues on the next page...

USBCx_CTRL field descriptions (continued)

Field	Description
	1 Interrupt Enabled 0 Interrupt Disabled
9 PM	USB Power Mask 1 The USBPWR and OC pins are not used by the USB core. 0 The USBPWR pin will assert with the USB core's Vbus power Enable and the assertion of the OC input will be reported to the USB core.
8 OVER_CUR_ POL	USB Polarity of Overcurrent 1 Low active 0 High active
7 OVER_CUR_DIS	Disable USB Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection

31 UTMI_CLK_VLD	UTMI PHY Clock Valid. This bit indicates that UTMI clock is valid. 0 UTMI Clock is invalid 1 UTMI Clock is valid
30–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CHRGDET	UTMI PHY chrgdet. Charger detector output. Actual circuit is not present. It is a self powered USB, we do not need charger circuitry but these bits are present to allow software compatibility.

Table continues on the next page...

USBCx_PHY field descriptions (continued)

Field	Description
	NOTE: Maximum response time = 1us 0 When a Host is detected 1 When a charger is detected
1 CHRGDET_INT_ EN	Charger detected interrupt enable. Actual circuit is not present. It is a self powered USB, we do not need charger circuitry but these bits are present to allow software compatibility. 0 Disable 1 Enable
0 CHRGDET_INT_ FLG	Charger detected interrupt flag. This bit is cleared when CHRGDET_INT_EN is 0. Actual circuit is not present. It is a self powered USB, we do not need charger circuitry but these bits are present to allow software compatibility. 0 No charger detected interrupt 1 Charger detected interrupt occurred

44.4 Core Registers

USBx_GPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–0 GPTLD	General Purpose Timer Load Value These fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

44.4.8 General Purpose Timer #0 Controller (USBx_GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USB Status Register (USB_USBSTS)), interrupt enable bit is TIE0 bit in n_USBINTR register. (See Interrupt Enable Register (USB_USBINTR) .)

Address: Base address + 84h offset

Field	Description
31–24 -	This field is reserved. Reserved
23–0 GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

44.4.10 General Purpose Timer #1 Controller (USBx_GPTIMER1CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI1 bit in UOG_USBSTS register (See USB Status Register (USB_USBSTS)), interrupt enable bit is TIE1 bit in n_USBINTR register (See Interrupt Enable Register (USB_USBINTR)).

Address: Base address + 8Ch offset

USBx_HCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR)
15–12 N_CC	Number of Companion Controller (N_CC). These bits are '0000b' in both the controller cores. 0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.
11–8 N_PCC	Number of Ports per Companion Controller For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC.
7–5 -	This field is reserved. Reserved
4 PPC	Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
3–0 N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because both the controller cores are Single-Port Host.

44.4.15 Host Controller Capability Parameters (USBx_HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: Base address + 108h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBx_USBCMD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames 0x20 32 micro-frames 0x40 64 micro-frames
15 FS2	See also bits 3-2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. **NOTE:** This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
14 ATDTW	Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13 SUTW	Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USB Device Mode (USB_USBMODE)) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
12 -	This field is reserved. Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to '1b' in this implementation.
10 -	This field is reserved. Reserved
9–8 ASP	Asynchronous Schedule Park Mode Count - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in all 4 controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
3–2 FS1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop. Host operation mode: When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.

44.4.19 USB Status Register (USBx_USBSTS)

This register indicates various states of the Host/Device controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: Base address + 144h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBx_USBSTS field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.

Table continues on the next page...

USBx_USBSTS field descriptions (continued)

Field	Description
	This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	Reclamation - Read Only. This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCHalted - Read Only. This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core. This is because OTG core is not operating as host in default. Please see CM bit in UOG_USBMODE register.
11 -	This field is reserved. Reserved
10 ULPII	ULPI Interrupt - R/WC. This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLI	DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SOF Received - R/WC. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.
5 AAI	Interrupt on Async Advance - R/WC.

Table continues on the next page...

USBx_USBSTS field descriptions (continued)

Field	Description
	System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4 SEI	System Error- R/WC. This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	Frame List Rollover - R/WC. The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the UOG_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	Port Change Detect - R/WC. The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/ Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.
1 UEI	USB Error Interrupt (USBERRINT) - R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set The device controller detects resume signaling only.
0 UI	USB Interrupt (USBINT) - R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

44.4.20 Interrupt Enable Register (USBx_USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable This bit is usable only if the controller supports UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_UOG_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enalbe When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

44.4.21 USB Frame Index (USBx_FRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce-undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

USBx_DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). **NOTE:** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
23–0 -	This field is reserved. Reserved

44.4.24 Next Asynch. Address (USBx_ASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: Base address + 158h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
7–0 RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

44.4.27 TX FIFO Fill Tuning (USBx_TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

Address: Base address + 164h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBx_TXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in UOG_USBMODE register is set. Default value is '00h' for OTG controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is '08h' for OTG controller core.
7–0 TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for

Table continues on the next page...

USBx_TXFILLTUNING field descriptions (continued)

Field	Description
	this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core.

44.4.30 Port Status & Control (USBx_PORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see Host Controller Structural Parameters (USB_HCSPARAMS)). Software could read this parameter register to determine how many ports need service.

Both the controller cores are Single-Port Host, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A device controller has only port register one (PORTSC1) and it does not support power control. Port control in device mode is only used for status port reset, suspend, resume, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Address: Base address + 184h offset

USBx_PORTSC1 field descriptions

Field	Description
31–30 PTS2	Parallel Transceiver Select (bit25, bit31, bit30). These register bits are implementation dependent. Field {bit25, bit31, bit30}. This need to be set to 3'b000. As such, its reset value is 3'b000.
29 STS	1 Serial Interface Engine is selected When this bit is set '1b', serial interface engine will be used instead of parallel interface signals.
28 PTW	Parallel Transceiver Width This bit has no effect if serial interface engine is used. These register bits are implementation dependent. It is Read-Only. Reset value is '1b'. 0 Reserved 1 Select the 16-bit UTMI interface [30 MHz]
27–26 PSPD	Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 Full Speed 01 Low Speed 10 High Speed 11 Undefined
25 PTS1	See description at bits 31-30
24 PFSC	Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 1 Forced to full speed 0 Normal operation
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. **NOTE:** The PHY clock cannot be disabled if it is being used as the system clock.

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
	In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signaled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 1 Disable PHY clock 0 Enable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero or in device mode.
20 WKCN	Wake on Connect Enable (WKCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero or in device mode.
19–16 PTC[3:0]	Port Test Control - Read/Write. Default = 0000b. Refer to Section 4.14 for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE:** *Low speed operations are not supported as a peripheral device.* Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved
15–14 PIC[1:0]	Port Indicator Control - Read/Write. Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if *Port Power* is zero. Bit Value Meaning

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
	00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Always = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported, therefore this bit will always be 0.
12 PP	Port Power (PP)-Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1b *Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.* 1 1b/0b - *Read/Write. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.* When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in both the controller cores (PPC = 1).
11–10 LS[1:0]	Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00 SE0 10 J-state 01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. **NOTE:** HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0.

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
	When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero.
7 SUSP	Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress. The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, *Port enabled* bit is a zero) the results are undefined. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/ driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.* Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation and clear the bit when the port control state switches to HS or FS idle. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. This bit is not-EHCI compatible. In Device mode:

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
	After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: This bit is undefined in device controller mode.

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
0 CCS	Current Connect Status-Read Only. In Host Mode: 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

44.4.31 On-The-Go Status & control (USBx_OTGSC)

It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status input register, or cause an OTG interrupt.

See also USB Device Mode (USB_USBMODE) register.

31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 1MSSE	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 1MSS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC).

Table continues on the next page...

USBx_OTGSC field descriptions (continued)

Field	Description
	Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 1msT	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7–6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resister; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.

Table continues on the next page...

USBx_USBMODE field descriptions (continued)

Field	Description
	Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE:** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB_TXFILLTUNING) and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. **NOTE:** The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USB Command Register (USB_USBCMD) .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The field in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 Little Endian [Default] 1 Big Endian
1–0 CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/ device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '10b'. Bit Meaning 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

44.4.33 Endpoint Setup Status (USBx_ENDPTSETUPSTAT)

Address: Base address + 1ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.

44.4.39 Endpoint Controln (USB*x*_ENDPTCTRL*n*)

There is a UOG_ENDPTCTRLx register for each endpoint in a device.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is bulk, isochronous, or interrupt-types). Leaving an

unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: Base address + 1C4h offset + (4d × i), where i=0d to 4d

19–18 TXT	TX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX Endpoint Data Source - Read/Write 0 Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It is cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues to returning STALL until this bit is either cleared by software or automatically cleared as above. **NOTE:** For CONTROL type endpoint, there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. Take care that the STALL bit is not set immediately after writing a '1' to it. Please follow this procedure: continually write this STALL bit until it is set or until a new setup has ben received by checking the associated ENDPTSETUPSTAT bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 -	This field is reserved. Reserved.
3–2 RXT	RX Endpoint Type - Read/Write 00 Control

Table continues on the next page...

USBx_ENDPTCTRL*n* field descriptions (continued)

Field	Description
	01 Isochronous 10 Bulk 11 Reserved
1 RXD	RX Endpoint Data Sink - Read/Write - TBD 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It is cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint, Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues to returning STALL until this bit is either cleared by software or automatically cleared as above.

44.5 Functional description

These sections describe the functionality of the various building blocks of the USB.

44.5.1 USB dual role device/host controller

The USB Dual Role controller is an EHCI-compatible USB core which supports High Speed / Full Speed / Low Speed operation.

The USB controller core supports HS/FS/LS operation in Host mode and HS/FS operation in device mode.

44.5.1.1 Host mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

44.5.1.2 Peripheral (Device) Mode

- Up to 6 bidirectional endpoints
- High/Full speed operation
- Remote wake-up capable

44.5.2 USB Power Control Block

The USB controller supports low-power suspend and wake-up functionality. The power control block allows for placing the transceiver in low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of low power mode when needed. Additionally, the power control block can wake-up the ARM platform from sleep mode by generating an interrupt.

44.5.2.1 Entering Low Power Suspend mode

Low Power Suspend mode is always entered under the control of the driver software by setting the appropriate bit in USB core register PORTSC1. Once the controller is suspended, the clocks to the USB can be stopped.

44.5.2.2 Wake-up events

The power control block monitors the USB bus when the USB core is in the suspend state. Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) can be generated to ARM platform if related wake-up interrupt enable bit is set. This interrupt also re-activates the ARM platform clocks if they were stopped during the suspend.

44.5.2.2.1 Host mode events

The Host controller wakes-up on the following events:

- Remote wake-up request

A peripheral can request the host to re-activate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when J-K transition on DM/DP line is detected.

- Wake-up on overcurrent

If wake-up on overcurrent is enabled (WKOC bit in USB core register PORTSC1 is set to 1), the power control block sends a wake-up request to the USB core when over-current event is detected.

- Wake-up on disconnect

If wake-up on disconnection is enabled (WKDC bit in USB core register PORTSC1 is set to 1), the power control block sends a wake-up request to the USB core when disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-up on connect

If wake-up on connection is enabled (WKCN bit in USB core register PORTSC1 is set to 1), the power control sub-block sends a wake-up request to the USB core when connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, and WKCN, please see Port Status & Control (USB_PORTSC1).

44.5.2.2.2 Device mode events

When the OTG controller is configured for peripheral operation, the power control block sends a wake-up request to the USB core when any non-IDLE state is detected on the USB bus.

NOTE

Wake Up from USB needs following configuration:

1. REFTOP inside ANADIG must be ON in stop mode (required for Device Mode).
   - If ANATOP_STOP_MODE is used for stop mode (ANATOP_STOP_MODE bit is set in CCM Low Power Control Register), then 'stop_mode_config bit' in “ANADIG_ANA_MISC0” register inside ANADIG must be set to ‘1’.
   - If ANATOP_STOP_MODE is NOT used for stop mode, then keep “reftop_pwd” bit to ‘0’ in “anadig_anamisc0” register inside ANADIG.
2. Either Main Regulator OR Weak Regulator (1P1 & 2P5) must be ON in stop mode.

- If ANATOP_STOP_MODE is used for stop mode (ANATOP_STOP_MODE bit is set in CCM Low Power Control Register), then “enable_weak_linreg” bit in “anadig_reg2p5” register inside ANADIG must be set to ‘1’.
- If ANATOP_STOP_MODE is NOT used for stop mode, then either enable Weak Regulators 1P1 & 2P5 (set “enable_weaklinreg” bit in “anadig_reg2p5” register inside ANADIG) or enable Main regulators 1P1 & 2P5 (set “enable_linreg” bit in “anadig_reg1p1” & “anadig_reg1p1” registers inside ANADIG). To reduce power consumption in stop mode, main regulators are turned off, and weak regulators are turned on to support wake-up from USB.

44.5.3 Interrupts

44.5.3.1 USB core interrupts

Each USB core uses one dedicated vector in the interrupt table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB cores. Refer to the Interrupt Enable Register (USB_USBINTR) for details.

44.5.3.2 USB wake-up interrupts

Each USB core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but use the same vector as the corresponding USB controller cores' interrupt. These interrupts are generated by the Power Control blocks, which run on the 32 KHz standby clock.The wake-up interrupt is designed to work even when the USB and ARM platform clocks are disabled, such that a wake-up condition on the USB bus can reactivate the ARM platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the ARM platform clock. The software should than wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow

sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

44.6 USB operation model

This section describes the detailed application knowledge for OTG ports. It can be generally divided in two parts, one for Host and the other for Device. The Host part applies to the OTG ports when operating in Host mode. The Device part applies to the OTG ports when operating in Device mode.

44.6.1 Register interface

Slave accesses from the controlling processor enables access to the configuration, control, and status registers. One function of the system address map is the registers base address, which must begin on a 32-bit boundary. Register offset definitions are listed in the table below.

Configuration, control and status registers are divided into three categories: identification, capability, and operational registers.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read-only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are comprised of dynamic control or status registers that may be read only, read/write, or read/write to clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

Table 44-145 describes the interface register sets.

Table 44-145. Interface register sets

Offset	Register Set	Explanation
000h-07Ch	Identification registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability registers	Capability registers specify the limits, restrictions, and capabilities of a host/ device controller implementation. These values are used as parameters to the host/device controller driver.

Table continues on the next page...

44.6.1.2 Identification registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

44.6.2 Host data structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware). The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) support for the host controller interface. The asynchronous list is the root for all the bulk and control transfer type support. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

44.6.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB_PERIODICLISTBASE address register and the USB_FRINDEX register. The periodic schedule is based on an array of pointers called the Periodic Frame List. The USB_PERIODICLISTBASE address register is combined with the USB_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

Figure 44-140 shows the organization of periodic schedule.

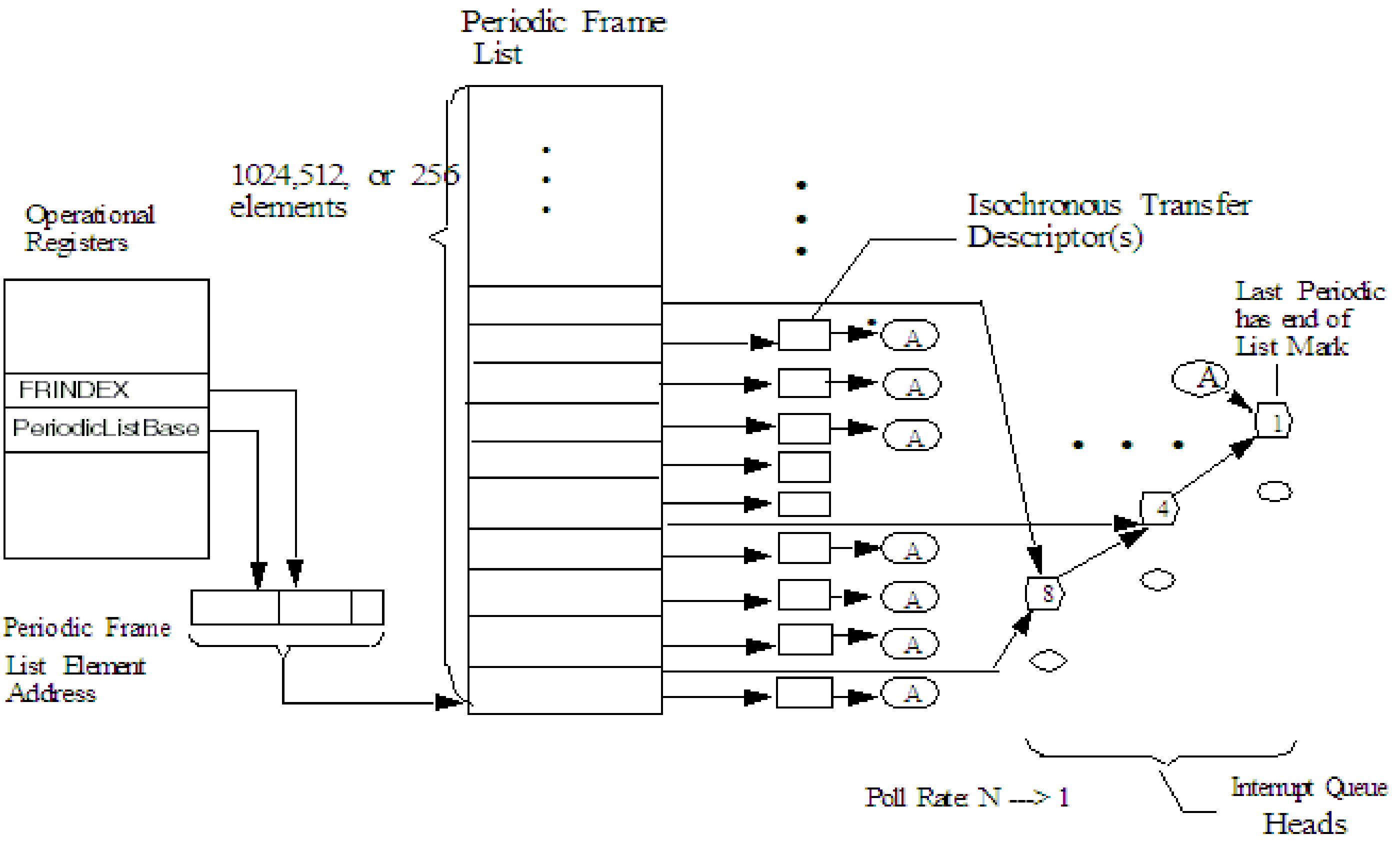

Figure 44-140. Periodic schedule organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 KB page-aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

Table 44-147 illustrates the format of the Frame list element pointer.

Table 44-147. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																											0		Typ			03-00H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 44-148. Typ field value definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor
11b	Frame Span Traversal Node

44.6.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all the control and bulk transfers are managed. Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

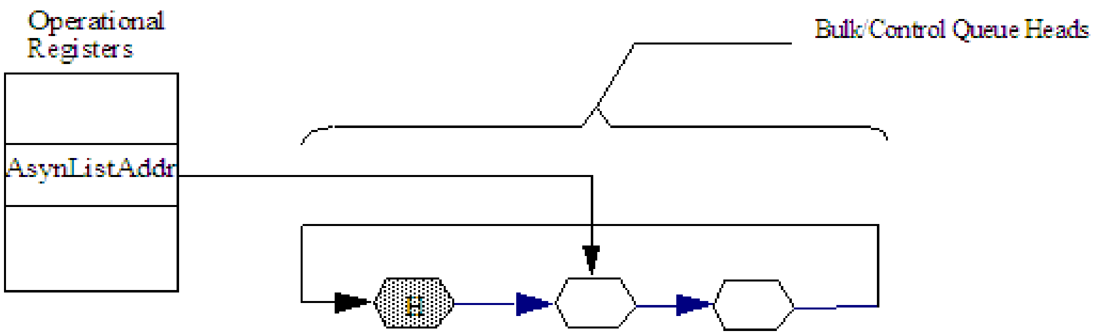

Figure 44-141. Asynchronous schedule organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

44.6.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in Table 44-149. This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 44-149. Isochronous Transaction Descriptor (iTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

These fields may be modified by the host controller if the I/O field indicates an OUT.

44.6.2.3.1 Next Link Pointer-Host Data Structures

The first DWord of an iTD is a pointer to the next schedule data structure. Table 44-150 describes the Next Schedule Element pointer field.

Table 44-150. Next Schedule Element pointer

Bit	Description
31-5	Link Pointer (LP). These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTD/siTD) or Queue Head (QH).
4-3	Reserved. These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1= Link Pointer field is not valid. 0= Link Pointer field is valid.

44.6.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status. Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the

Table 44-151 describes iTD Transaction Status and Control fields.

Table 44-151. iTD Transaction Status and Control

Bit	Description	
31-28	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16	Transaction X Length. For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).	
15	Interrupt On Complete (IOC). If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12	Page Select (PG). These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0	Transaction X Offset. This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

44.6.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous. Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

Tables below illustrate the field descriptions.

Table 44-152. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12	Buffer Pointer (Page 0). This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit reserved for future use and should be initialized by software to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 44-153. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12	Buffer Pointer (Page 1). This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0	Maximum Packet Size. This directly corresponds to the maximum packet size of the associated endpoint *(wMaxPacketSize)*. This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 44-154. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12	Buffer Pointer. This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2	Reserved. This bit reserved for future use and should be set to zero.

Table continues on the next page...

Table 44-154. iTD Buffer Pointer Page 2 (Plus) (continued)

1-0	Multi. This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame 10b Two transactions to be issued for this endpoint per micro- frame 11b Three transactions to be issued for this endpoint per micro- frame

Table 44-155. iTD Buffer Pointer Page 3-6

Bit	Description
31-12	Buffer Pointer. This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0	Reserved. These bits reserved for future use and should be set to zero.

44.6.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

Figure below shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 44-156. Split-transaction Isochronous Transaction Descriptor (siTD)

	Host Controller Read/Write		Host Controller Read Only.

44.6.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

Table 44-157 describes the Next Link Pointer fields.

Table 44-157. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Link Pointer field is not valid. 0=Link Pointer is valid.

44.6.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

Tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 44-158. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O).0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 44-159. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.

Table continues on the next page...

Table 44-159. Micro-frame Schedule Control (continued)

15-8	Split Completion Mask (mFrame C-Mask). This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

44.6.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer. Table 44-160 describes siTD transfer state fields.

Table 44-160. siTD Transfer Status and Control

Bit	Description	
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.	
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).	
29-26	Reserved. This field reserved for future use and should be set to zero.	
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)	
15-8	μFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.	
7-0	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
	6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 44-160. siTD Transfer Status and Control (continued)

Bit	Description	
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
	2	Missed Micro-Frame. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
	1	Split Transaction State (SplitXstate). The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
	0	Reserved. Bit reserved for future use and should be set to zero.

44.6.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. Table 44-161 describes the siTD buffer pointer fields.

Table 44-161. Buffer Page Pointer List (plus)

Bit	Description	
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K paged aligned, physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* specifies the *current* active pointer	
11-0	Page 0: Current Offset. The 12 least significant bits of the Page 0 pointer is the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field)). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero). The least significant bits of Page 1 pointer is split into three sub-fields Page 1:	
	Bits	Description
	11-5	Reserved

Table continues on the next page...

Table 44-161. Buffer Page Pointer List (plus) (continued)

Bit	Description	
	4-3	Transaction position (TP). This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning 00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full- speed that is greater than 188 bytes.transaction 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
	2-0	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

44.6.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD. This pointer cannot reference any other schedule data structure.

Table 44-162 describes the siTD back link pointer fields

.

Table 44-162. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

44.6.2.5 Queue Element Transfer Descriptor (qTD)

This data structure is only used with a queue head. This data structure is used for one or more USB transactions. This data structure is used to transfer up to 20480 (5*4096) bytes. The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. This structure is 32 bytes (or one 32-byte cache line). This data structure must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following field definitions of updates to the qTD are to the qTD portion of a queue head.

Table 44-163 shows the Queue head data structure.

Table 44-163. Queue Head Data Structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (page 0)																				-												1B-18H
Buffer Pointer (page 0)																				-												1F-1CH

(shaded)	Host Controller Read/Write		Host Controller Read Only.

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

44.6.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor. Table 44-164 describes Next qTD pointer fields.

Table 44-164. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

44.6.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next client buffer on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet. Table 44-165 describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 44-165. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

44.6.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

Table 44-166 describes the TD Token fields.

Table 44-166. TD Token (DWord 2)

Bit	Description	
31	Data Toggle. This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.	
30-16	Total Bytes to Transfer. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that *Total Bytes To Transfer* be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length. Although it is possible to create a transfer up to 20K this assumes the 1^{st} offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).	
15	Interrupt On Complete (IOC). If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12	Current Page (C_Page). This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.	
11-10	Error Counter (CERR). This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the *Halted* bit to a one, and error status bit for the error that caused *CERR* to decrement to zero. An interrupt is generated if the *USB Error Interrupt Enable* bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD. Error Decrement Counter Transaction Error Yes Data Buffer Error No[3] Stalled No[1] Babble Detected No[1] No Error No[2]	
	Error	Decrement Counter Error Decrement Counter
	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented
	2	If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and *PIDCode* indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset *CERR* to extend the total number of errors for this transaction. For example, *CERR* should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b. See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the *PIDCode* indicates a SETUP.
	3	Data buffer errors are host problems. They don't count against the device's retries.
	NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9-8	PID Code. This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)

Table continues on the next page...

Table 44-166. TD Token (DWord 2) (continued)

Bit	Description	
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, µ*Frame S-mask* field in
	11b	Reserved
7-0	Status. This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split- transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.

Table continues on the next page...

Table 44-166. TD Token (DWord 2) (continued)

Bit	Description	
	0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

44.6.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

Table 44-167 describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 44-167. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

44.6.2.6 Queue Head

Table 44-168 shows the Queue head structure layout.

Table 44-168. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

These fields are used exclusively to support split transactions to USB 2.0 Hubs

(shaded)	Host Controller Read/Write	(unshaded)	Host Controller Read Only.

44.6.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

Table 44-169 describes the Queue head DWord 0 fields.

Table 44-169. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

44.6.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint. There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

Table 44-170 describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 44-170. Endpoint Characteristics: Queue Head DWord 1

Bit	Description
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.
27	Control Endpoint Flag (C). If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.

Table continues on the next page...

Table 44-170. Endpoint Characteristics: Queue Head DWord 1 (continued)

Table 44-171 describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 44-171. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame 10b Two transactions to be issued for this endpoint per micro-frame 11b Three transactions to be issued for this endpoint per micro-frame
29-23	Port Number. This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.

Table continues on the next page...

Table 44-171. Endpoint Capabilities: Queue Head DWord 2 (continued)

15-8	Split Completion Mask (μFrame C-Mask). This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the μ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (μFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the μ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

44.6.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

Table 44-172 describes the current qTD link pointer field descriptions.

Table 44-172. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves an execution cache for the transfer.

Table 44-173 describes the Host-controller rules for bits in overlay.

Table 44-173. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt)µRW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	Data Toggle. The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This 2-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

44.6.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary. See Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table continues on the next page...

	Back Path Link Pointer																											0		Typ		T	07-04H

Table 44-174. Frame Span Traversal Node Structure Layout

	Host Controller Read/Write		Host Controller Read Only.

44.6.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

Table 44-175 describes the FSTN normal path pointer fields.

Table 44-175. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1=Link Pointer field is not valid. 0=Link Pointer is valid.

44.6.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head. If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

Table 44-176 describes the FSTN back path link pointer fields.

Table 44-176. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

44.6.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software). Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

44.6.3.1 Host Controller Initialization

When the system boots, the host controller is enumerated, assigned a base address for the register space and BIOS sets the USB_FLADJ register to a system-specific value. After initial power-on or HCReset (hardware or through HCReset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

Table 44-177 describes the default values of operational registers.

.

Table 44-177. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if *Asynchronous Schedule Park Capability is one*)
USB_USBSTS	00001000h
USB_USBINTR	00000000h

Table continues on the next page...

Table 44-177. Default Values of Operational Register Space (continued)

USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/*PPC* set to one); 00003000h (w/*PPC* set to zero)

To initialize the host controller, software should perform the following steps:

- Reset the controller by setting the USBCMD:RST bit and wait for it to clear. Configure the controller for HOST operation by setting USBMODE.CMD to 3.
- Program the USB_CTRLDSSEGMENT register with 4-Gbyte segment where all of the interface data structures are allocated.
- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled port enabled High-speed ports, but the schedules have not enabled. The EHCI Host controller do not transmit SOFs to enabled Full- or Low-speed ports. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNDLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

44.6.3.2 Port Routing and Control

A USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers. Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controller on this part does not require nor support companion controllers to support Full Speed/Low Speed devices. Therefore, no port routing is present in the controller. Please refer to Embedded Transaction Translator Function for detail!

Figure 44-142 illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

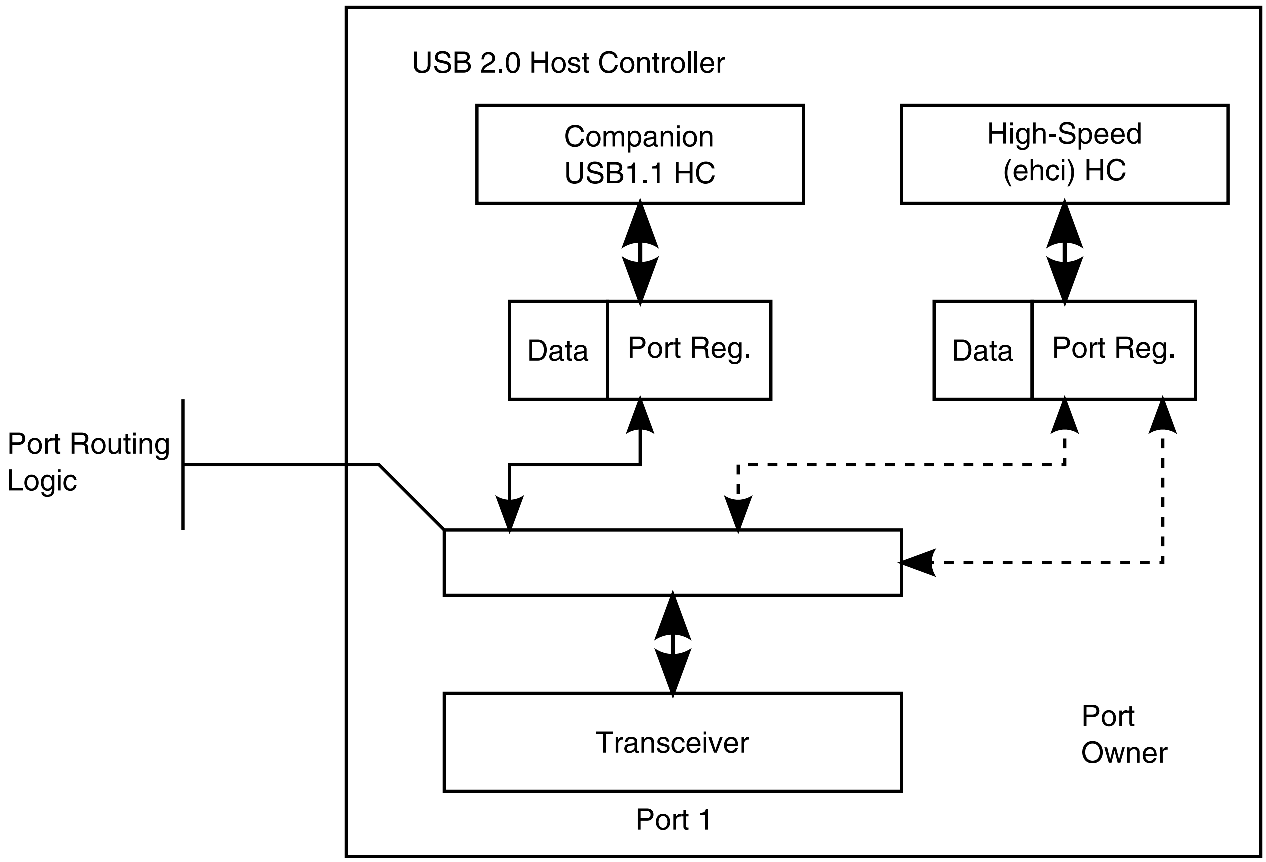

Figure 44-142. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.[4]

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See Host Controller Structural Parameters (USB_HCSPARAMS).

4. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

44.6.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller. The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

Table 44-178 summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 44-178. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see Port Status & Control (USB_PORTSC1)). The EHCI HC can temporarily release control of the port to a companion HC by setting the *PortOwner* bit in the PORTSC1 register to one.

44.6.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation. The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's

USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows

the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

44.6.3.2.3 Example Port Routing State Machine

Figure 44-143 illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

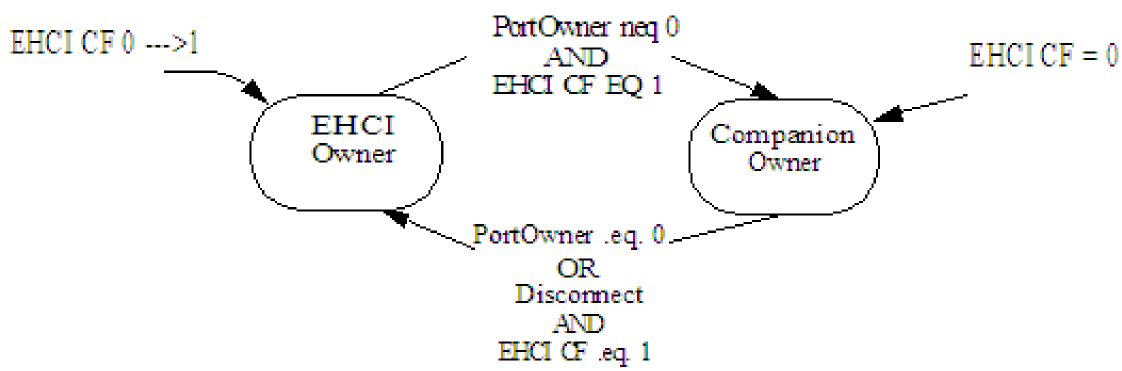

Figure 44-143. Port Owner Handoff State Machine

44.6.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.

- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

44.6.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occurs:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

44.6.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see Host Controller Structural Parameters (USB_HCSPARAMS)). When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

Table 44-179 describes the summary behavioral model.

Table 44-179. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description

Table continues on the next page...

Table 44-179. Port Power Enable Control Rules (continued)

0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

44.6.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit. The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.

- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 44-180 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

44.6.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub. Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the ARM platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

44.6.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see Port Status & Control (USB_PORTSC1)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 μsec. The port's

Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

Table 44-180 summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 44-180. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, theUSB_ PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

Table continues on the next page...

Table 44-180. Behavior During Wake-up Events (continued)

Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

44.6.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule. The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see Frame List Base Address (USB_PERIODICLISTBASE))/Device Address (USB_DEVICEADDR) The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host data structures. In each micro-frame, if the periodic schedule is enabled (see Periodic Scheduling Threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see Figure 44-144). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic

schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

Figure 44-144 illustrates the derivation of pointer into frame list array.

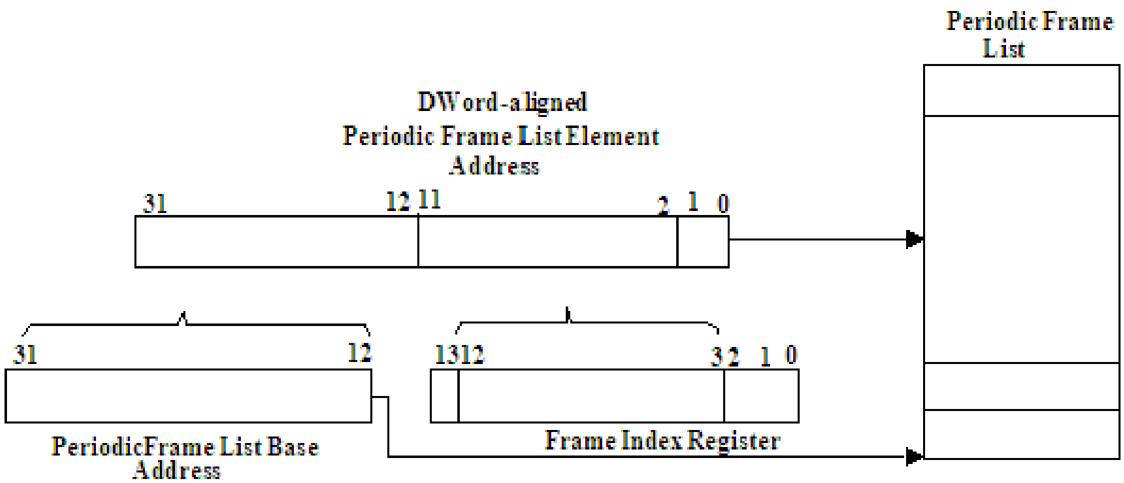

Figure 44-144. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see Figure 44-145.

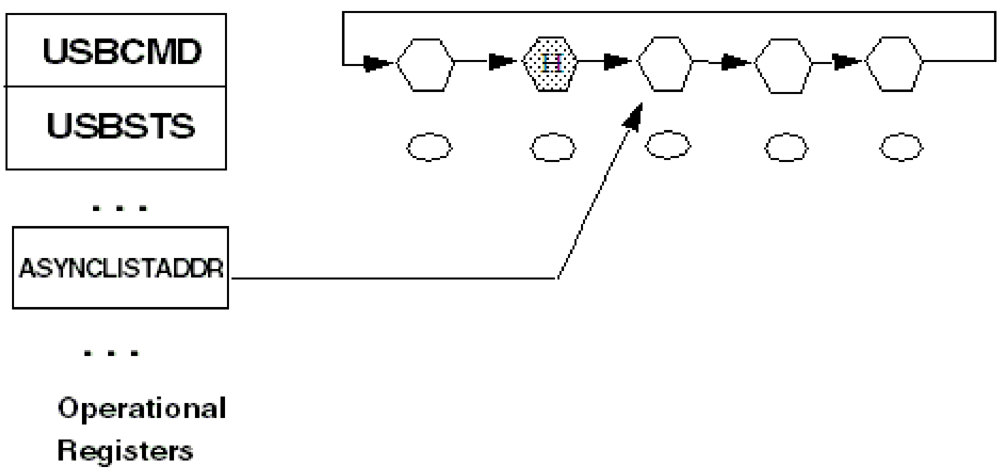

Figure 44-145. General Format of Asynchronous Schedule List

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the

USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous Schedule for complete operational details.

44.6.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries. For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

44.6.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction. This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 44-146. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function (*f*(*x*)) between the 80% and Last Start curves. The function *f*(*x*) adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

Figure 44-146 illustrates the Best-Fit Approximation.

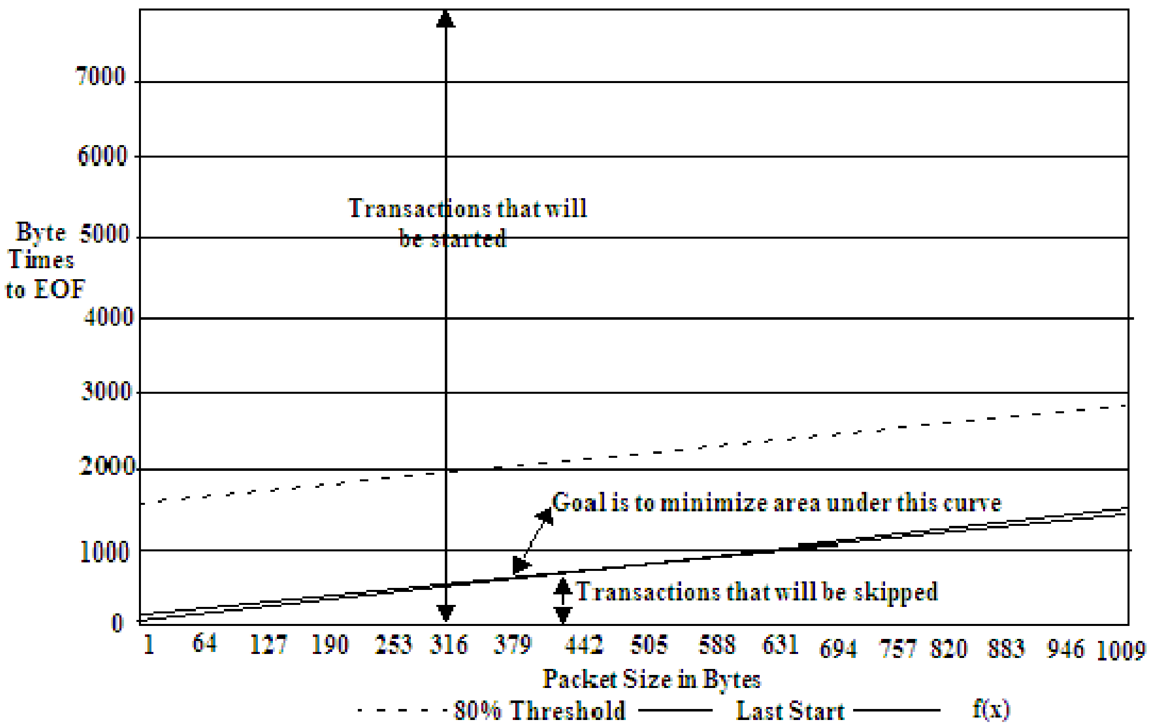

Figure 44-146. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in Table 44-181. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 44-181. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includessync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 44-146 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Alorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
     Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
     Rvalue = FALSE
End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the

running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the *f*(*x*) plot was getting close to the LastStart line.

44.6.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned. Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in Figure 44-147). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

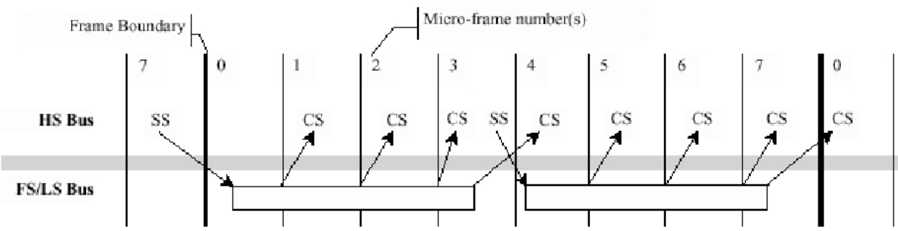

Figure 44-147. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as Figure 44-147 illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in USB Frame Index (USB_FRINDEX) and initially illustrated in Schedule Traversal Rules . Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in Figure 44-148.

This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

Figure 44-148 illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

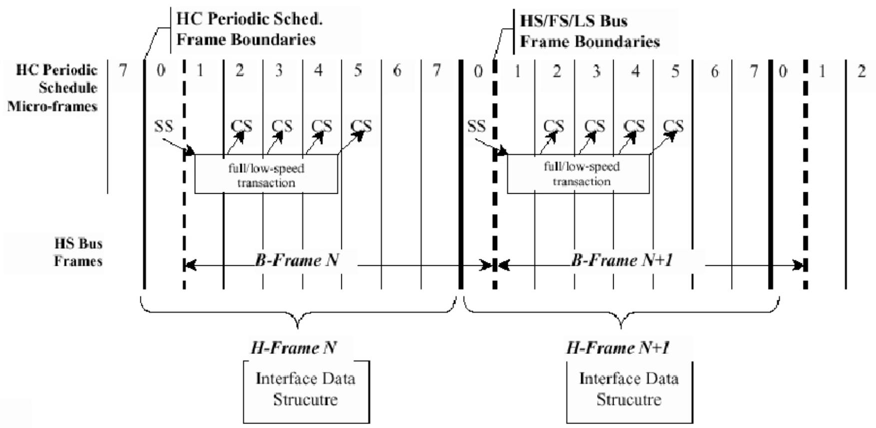

Figure 44-148. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in Figure 44-148 . The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in USB Frame Index (USB_FRINDEX), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. USB Frame Index (USB_FRINDEX) provides the requirements that software should adhere when writing a new value in FRINDEX.

Table 44-182 illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 44-182. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]

44.6.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule. The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero. The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to

determine when the periodic schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the

Figure 44-149 illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

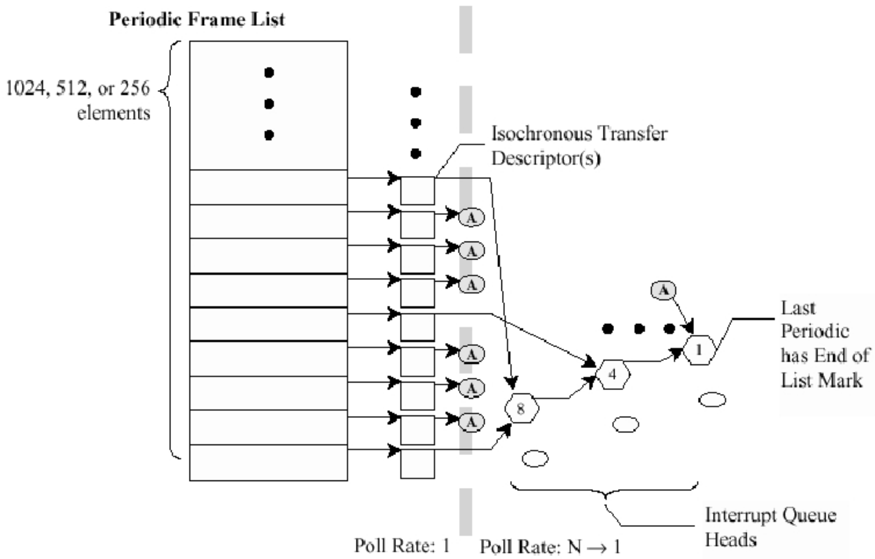

Figure 44-149. Example Periodic Schedule

44.6.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.

- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

44.6.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Each iTD can span 8 micro-frames worth of transactions. When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array. If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move

data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Sixe. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table

summary of the host controller required behavior for all the high-bandwidth transaction cases.

44.6.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

Figure 44-150 illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

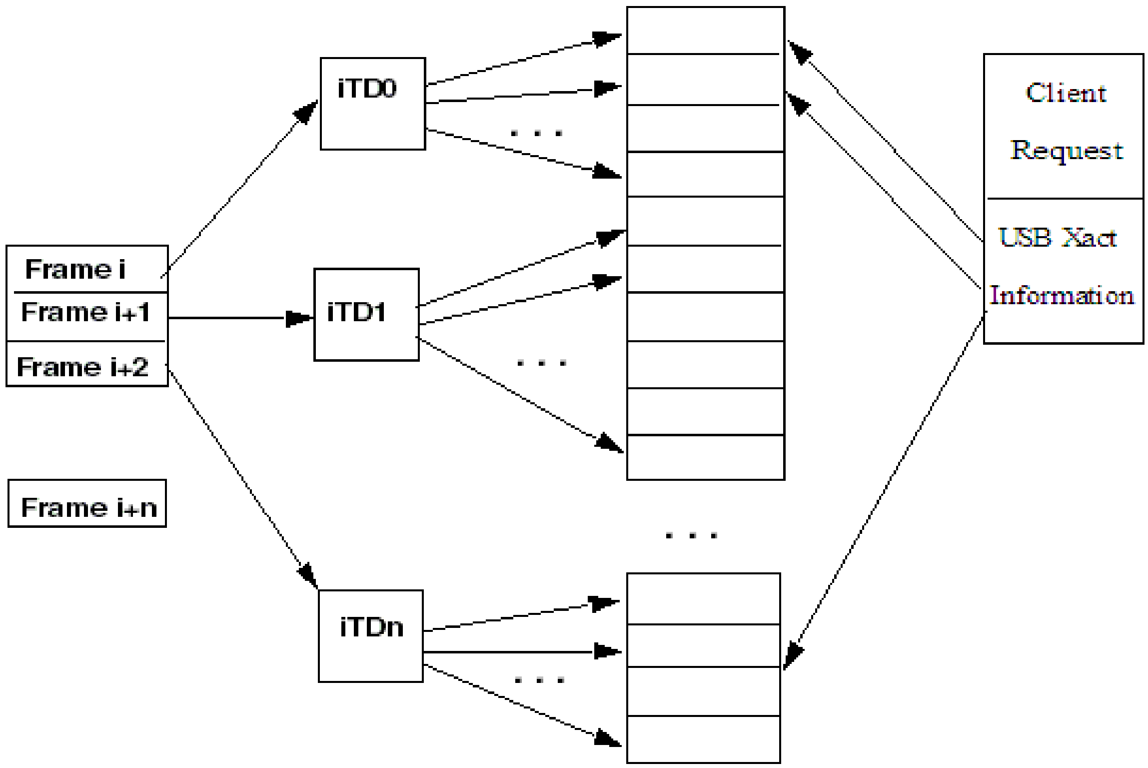

Figure 44-150. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

44.6.3.7.2.1 Periodic Scheduling Threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures. It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1 uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

44.6.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register. If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit is set to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty Asynchronous Schedule Detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 44-145. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

44.6.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section. There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD

pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadCurrent is a pointer to a queue head that is
          -- already in the active list
          -- pQHeadNew is a pointer to the queue head to be added
          --
          -- This algorithm links a new queue head into a existing
          -- list
          --
          pQueueHeadNew.HorizontalPointer  =  pQueueHeadCurrent.HorizontalPointer
          pQueueHeadCurrent.HorizontalPointer =  physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

44.6.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section. There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list. Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadPrevious is a pointer to a queue head that
          -- references the queue head to remove
          -- pQHeadToUnlink is a pointer to the queue head to be
          -- removed
          -- pQheadNext is a pointer to a queue head still in the
          -- schedule. Software provides this pointer with the
          -- following strict rules:
          --         if the host software is one queue head, then
          --         pQHeadNext must be the same as
          --         QueueheadToUnlink.HorizontalPointer. If the host
          --         software is unlinking a consecutive series of
          --         queue heads, QHeadNext must be set by software to
          --         the  queue head remaining in the schedule.
          --
          -- This algorithm unlinks a queue head from a circular list
          --
          pQueueHeadPrevious.HorizontalPointer =  pQueueHeadToUnlink.HorizontalPointer
```

```
                    pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

Figure 44-151 illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A & B). It is sufficient that the host controller

can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). Figure 44-151 illustrates the generic queue head unlink scenario.

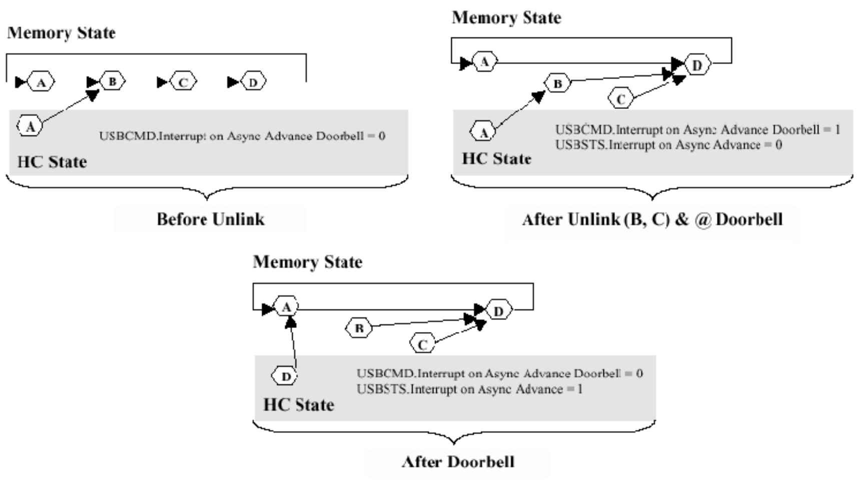

Figure 44-151. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

44.6.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty. The queue head data structure (see Table 44-168) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous Schedule Traversal: *Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in Figure 44-152

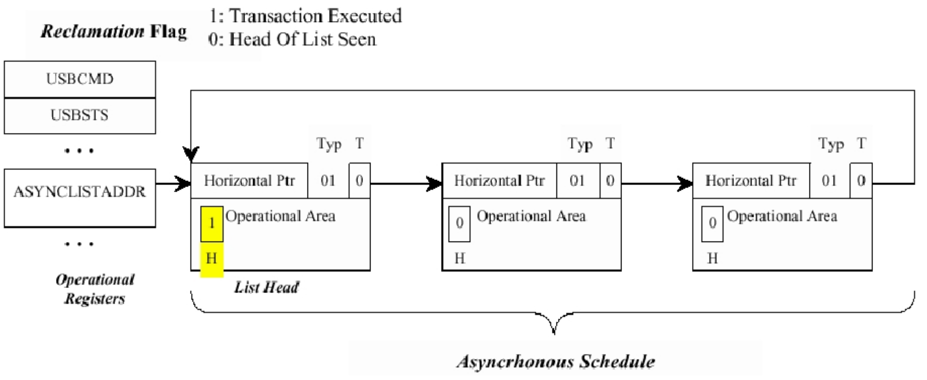

Figure 44-152. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

44.6.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame. It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

44.6.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 μsec. The value is derived based on the analysis in Example Derivation for *AsyncSchedSleepTime*, The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. Figure 44-153 illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

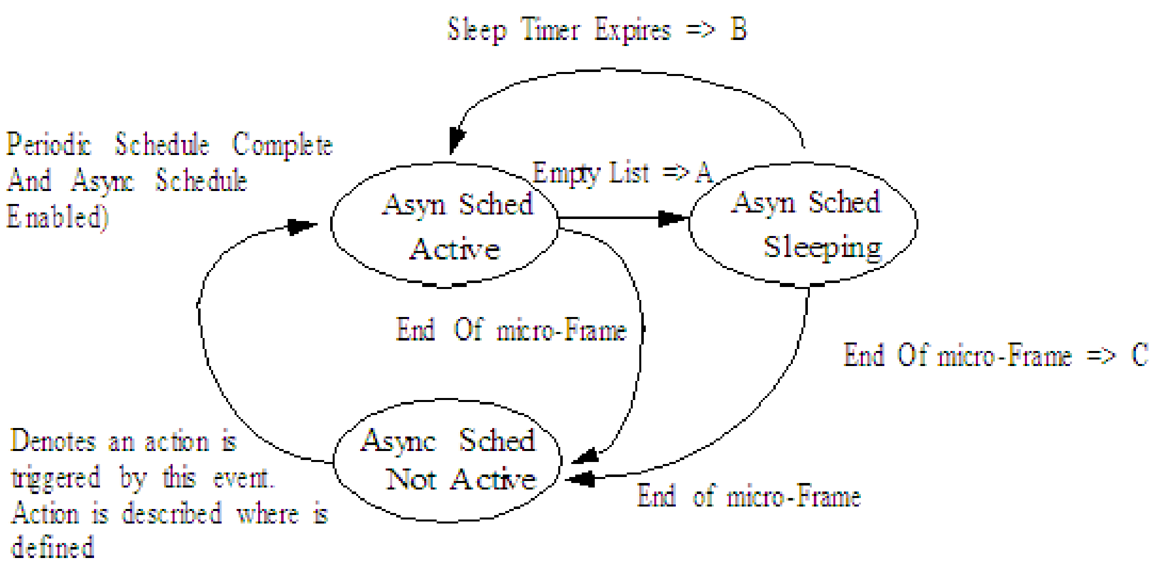

Figure 44-153. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in Figure 44-153 are defined in Table 44-183.

Table 44-183. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

44.6.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

44.6.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsyncrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

44.6.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

44.6.3.8.4.5 Example Derivation for *AsyncSchedSleepTime*

The derivation is based on analysis of what work the host controller could be doing next. It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

Table 44-184 summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 44-184. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 μs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 μs sleep period would allow the host controller to get the NAK results on the first complete-split.

44.6.3.8.5 Asynchronous Schedule Traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame. In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting Asynchronous Schedule Before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous

schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or

- The asynchronous schedule traversal restarts from a sleeping state (see Restarting Asynchronous Schedule Before EOF).

44.6.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty Asynchronous Schedule Detection) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch Queue Head).

It is required that the host controller sets the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in Asynchronous Schedule Traversal: *Start Event*, occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute Transaction). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

44.6.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head (see Queue Head Initialization). Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in Table 44-185 The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

Table 44-185 describes the NakCnt field adjustment rules.

Table 44-185. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1, 1] Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Nak Count Reload Control .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see Empty Asynchronous Schedule Detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Asynchronous Schedule Traversal: *Start Event*. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

44.6.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Execute Transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Table 44-168) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Asynchronous Schedule Traversal: *Start Event* for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 44-152).

Figure 44-154 illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (Figure 44-154). The host controller does not perform the nak counter reload operation if the RL field (see Table 44-168) is set to zero.

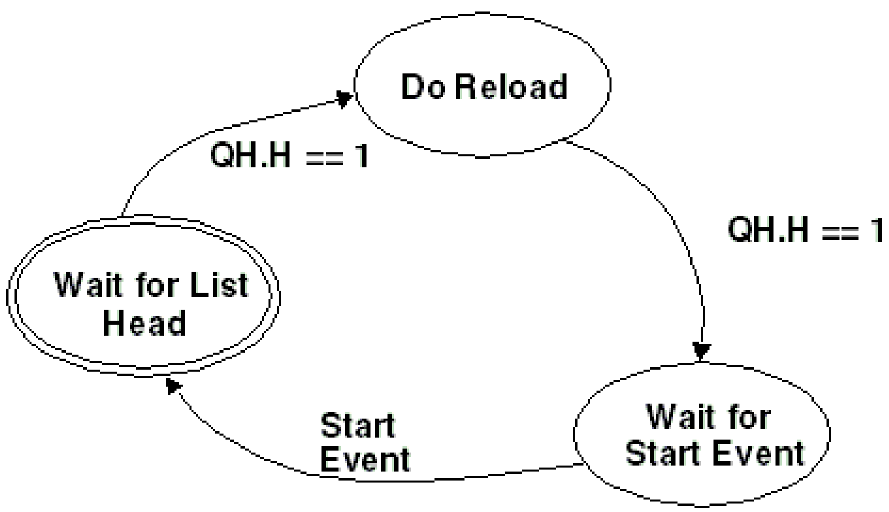

Figure 44-154. Example HC State Machine for Controlling Nak Counter Reloads

44.6.3.9.1.1 Wait for List Head

This is the initial state. The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous Schedule Traversal: *Start Event* occurs. The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule. This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

44.6.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

44.6.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

44.6.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 44-168). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in Figure 44-155. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. Figure 44-155 illustrates the Host Controller Queue Head Traversal State Machine.

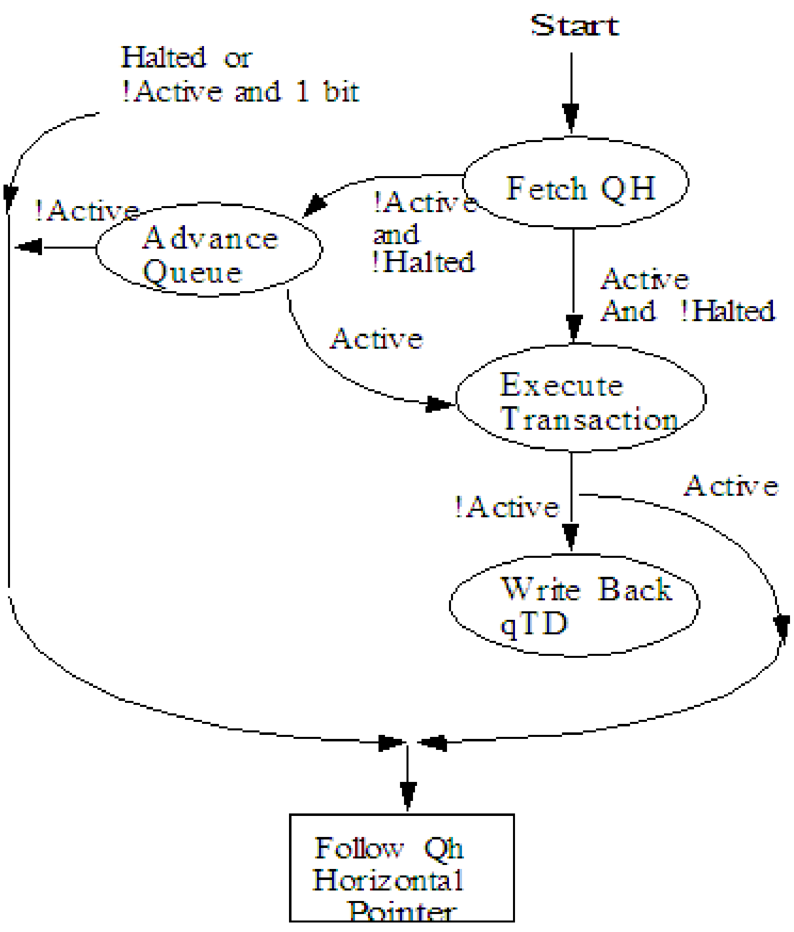

Figure 44-155. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute Transaction) describes the basic requirements for all endpoints. Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

44.6.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see Next Asynch. Address (USB_ASYNCLISTADDR))/ Endpoint List Address (USB_ENDPTLISTADDR) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Table 44-168.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty Asynchronous Schedule Detection) and Nak Counter reloads (see Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.

44.6.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 44-170).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

44.6.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Split Transactions for Asynchronous Transfers and Split Transaction Interrupt .

44.6.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it. For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

44.6.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria:

The pre-operation is:

Checks the Nak counter reload state (Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

44.6.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is

toggled, the current page offset is advanced to the next appropriate value (for example, advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Buffer Pointer List Use for Data Streaming with qTDs .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Transaction Error .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

44.6.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt). The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB.USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset,* and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB.USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB.USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

44.6.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule. This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB.HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB.USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB.USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB.USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute Transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asyncrhonous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

Table 44-186 summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 44-186. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	

Table continues on the next page...

Table 44-186. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. [1],, [2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. [2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

44.6.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero. The source data for the write-back is the transfer results area of the queue head overlay area (see Table 44-186). The host controller uses the *Current qTD Pointer* field as the target address for the qTD. The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

NOTE

If the retired qTD is the last one on the linked list (Terminate bit set on link pointers), then the host controller will read it one more time to check if the driver software updated the link pointers. If the memory holding the last qTD is re-used by software before the controller has read the qTD, the host controller may incorrectly use that data as a valid qTD and

perform incorrect actions or even crash. For this reason, driver software should not remove the last qTD from the linked list.

44.6.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

44.6.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*. This means: if the buffer spans more than one physical page, it must obey the following rules (Figure 44-156 illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

Figure 44-156 illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

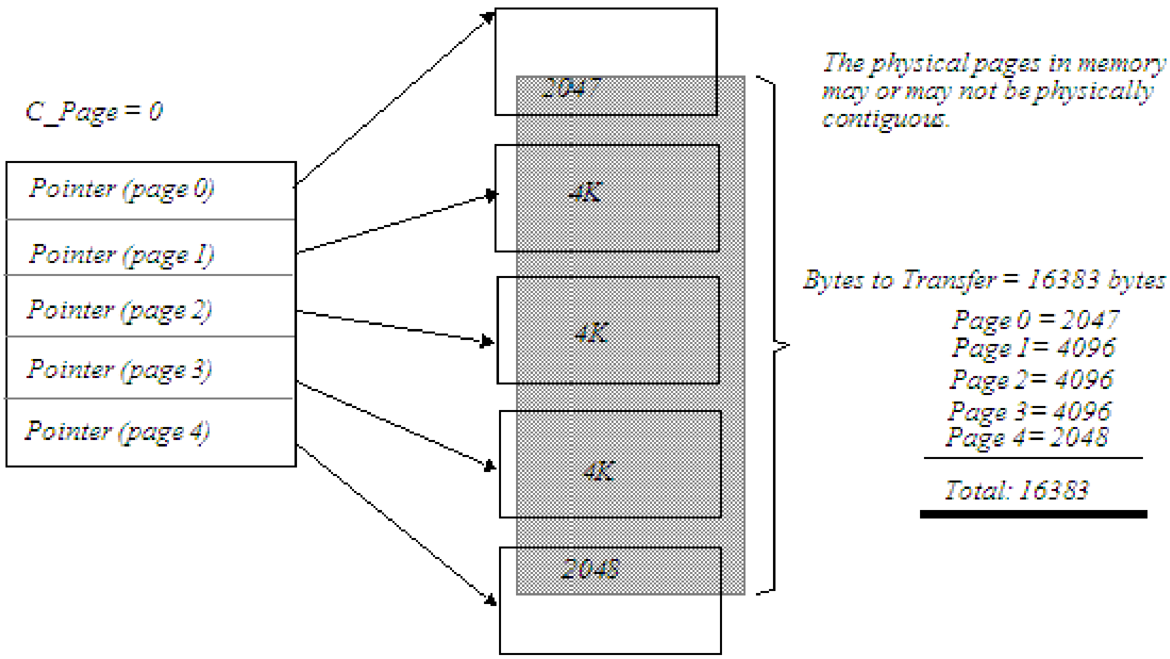

Figure 44-156. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4^{th} transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4^{th} transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the

overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.
- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

44.6.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate. System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame with-in 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in Table 44-187.

Table 44-187. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on *S-Mask* = 01h	A queue head for the *bInterval* of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

44.6.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to one, or whenever a transfer (qTD) completes with a short packet. If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

44.6.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints. Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see Table 44-188).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

Table 44-188 illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 44-188. Ping Control State Transition Table

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr[1]	Do Ping
Do Ping	PING	Stall	N/C[2] Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT

Table continues on the next page...

Table 44-188. Ping Control State Transition Table (continued)

Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C[2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 44-189. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

44.6.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs. This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol. Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue Head). The interface data structures need to be programmed with the device address and the

Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

44.6.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head. All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

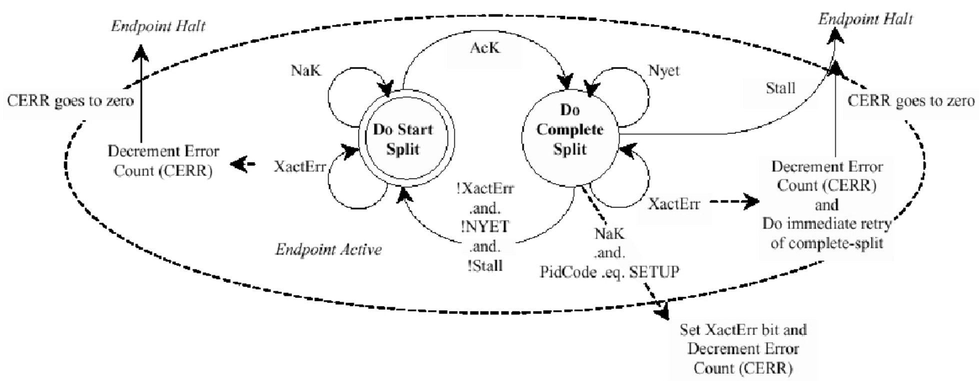

Figure 44-157. Host Controller Asynchronous Schedule Split-Transaction State Machine

44.6.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

44.6.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing Control/Bulk/Interrupt Transfers through Queue Heads).

44.6.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule. Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete),

but the remainder of the operational framework is intact. This means that the transfer advancement, and so on. occurs as defined in Managing Control/Bulk/Interrupt Transfers through Queue Heads, but only occurs on the completion of a split transaction.

44.6.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field. The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

Figure 44-158 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^{C}X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

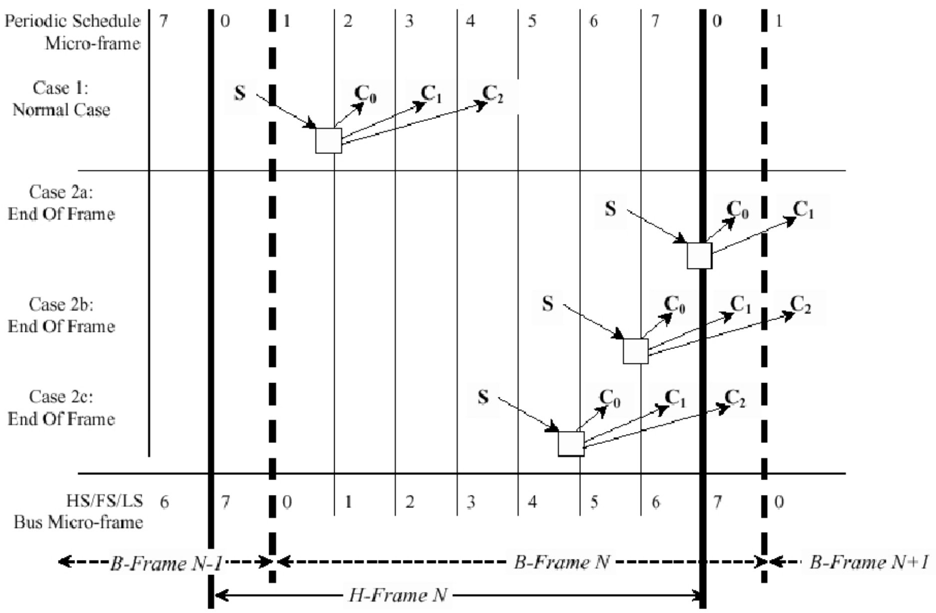

Figure 44-158. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

Figure 44-159 illustrates the general layout of the periodic schedule.

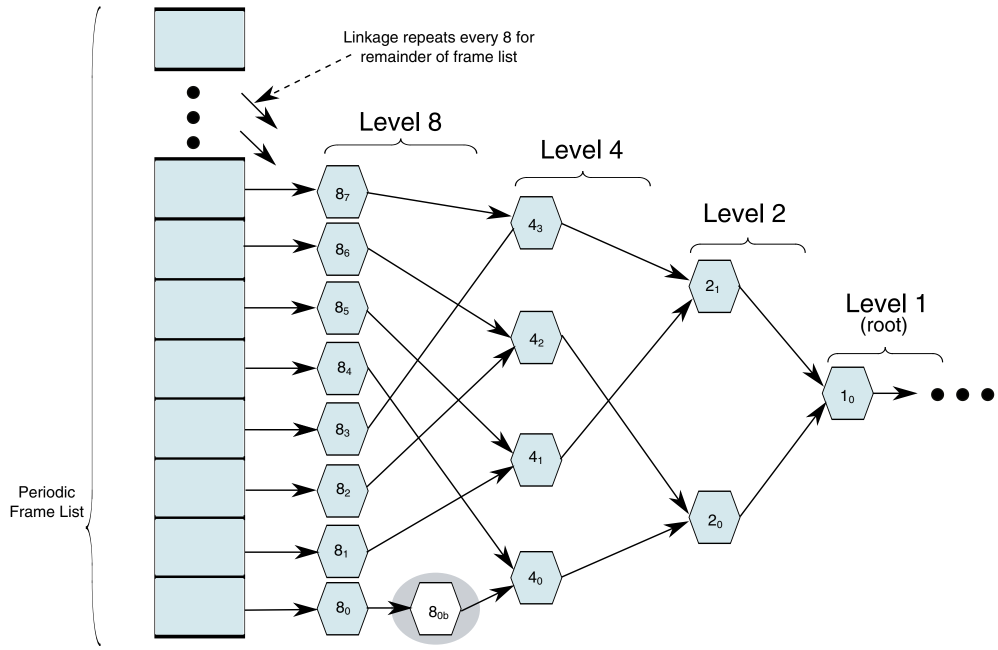

Figure 44-159. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to

8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see Table 44-166). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 44-158, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 44-158, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

44.6.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c). An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.
- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See Execute Transaction and Tracking Split Transaction Progress for Interrupt Transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
    - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Periodic Isochronous - Do Complete Split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in Figure 44-160.

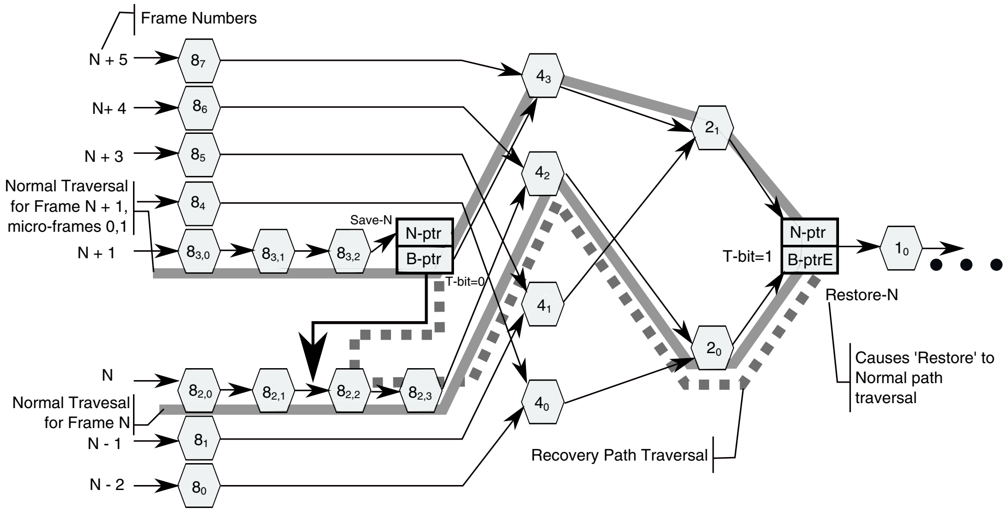

Figure 44-160. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in Figure 44-160 with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 }. The nodes on the recovery-path are bolded. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place*

FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 }.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 }.

44.6.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse. When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero.
    - *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth rebalance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

44.6.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost. For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline. When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.

- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

44.6.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit*. This is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, *cMicroFrameBit* = (1 shifted-left(*FRINDEX*[2:0])). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-splt transaction for the current micro-frame.

Figure 44-161 illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

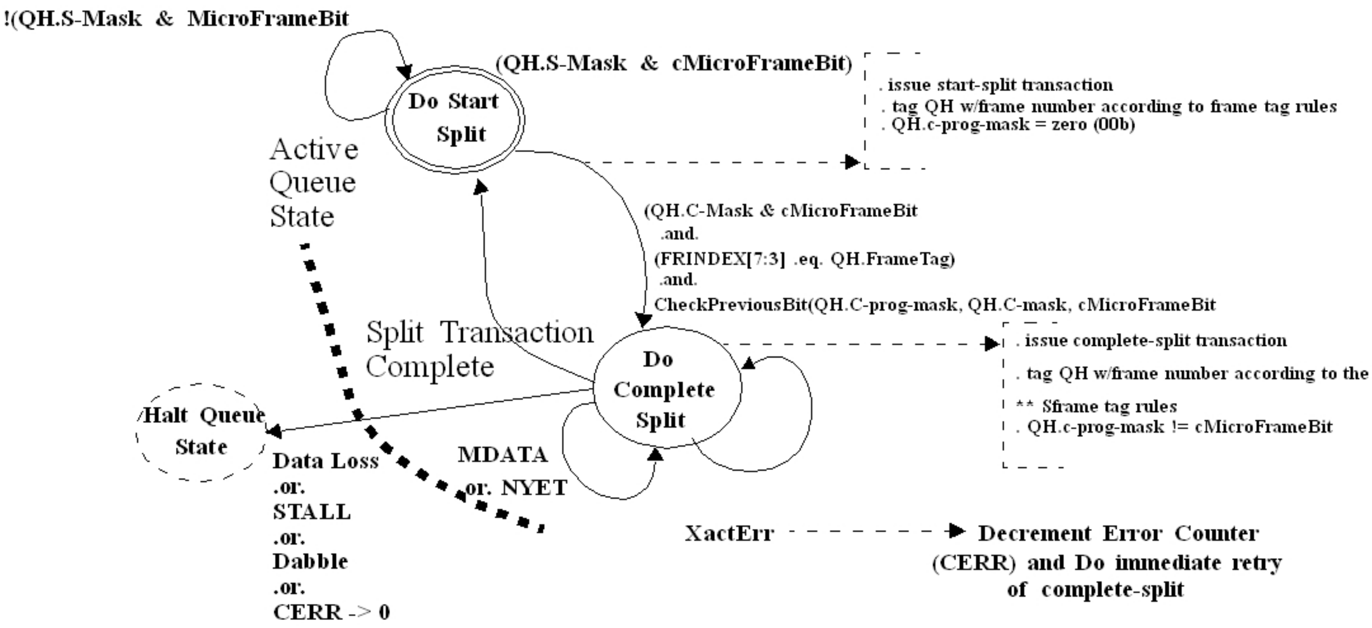

Figure 44-161. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous - Do Complete Split for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                               If not(previousBit bitAND QH.C-prog-mask) then
                    rvalue = FALSE;
          End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section Periodic Isochronous - Do Start Split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. Table 44-190 lists the possible combinations and the appropriate action.

Table 44-190. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.

Table continues on the next page...

Table 44-190. Interrupt IN/OUT Do Complete Split State Execution Criteria (continued)

D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 44-158).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 44-158).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 44-158).

44.6.3.12.2.6 Rebalancing the Periodic Schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation. This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then

wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

44.6.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions. This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

44.6.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur. The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. Figure 44-162 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{S}X and ^{C}X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

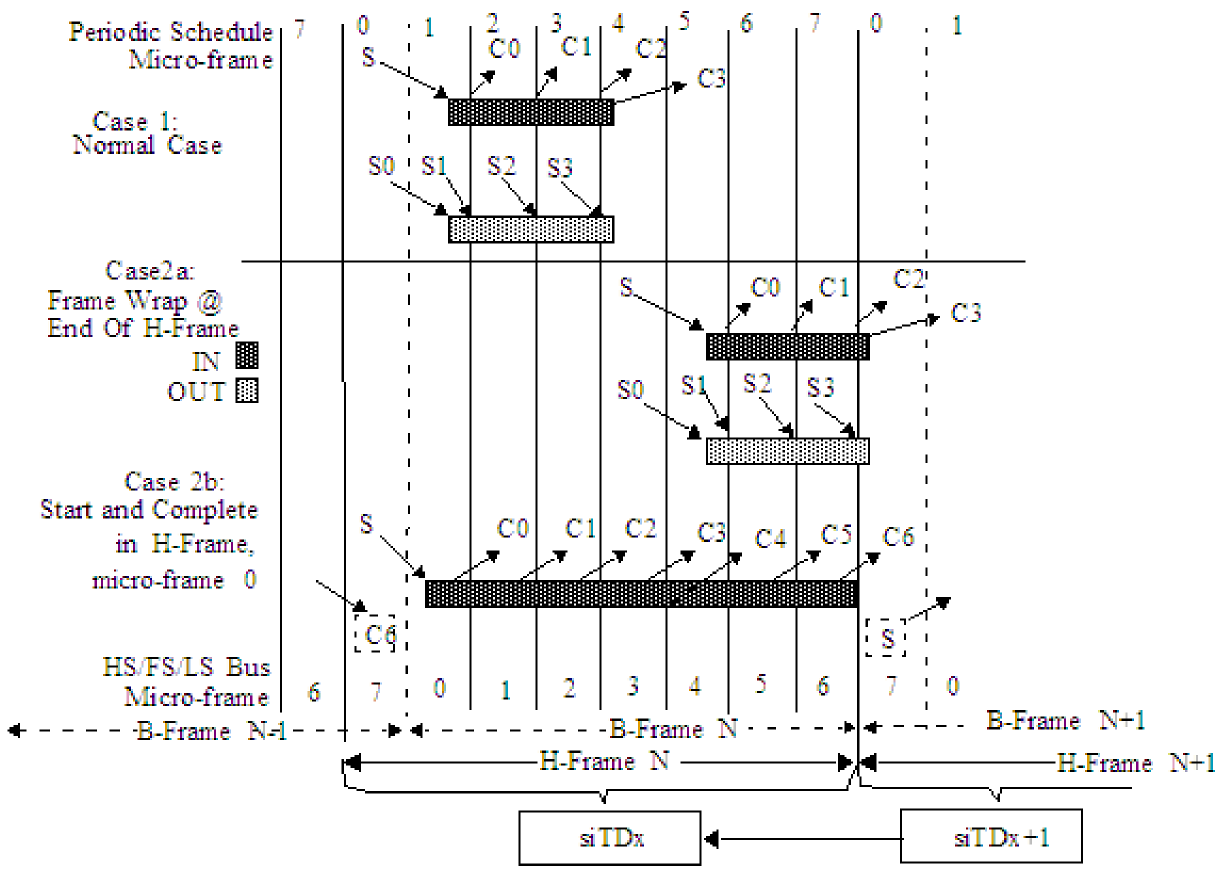

Figure 44-162. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.
- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame,* micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Figure 44-163). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt .
- *Frame S-mask*. This is a field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 44-162, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by USB.FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example

in Figure 44-162, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Complete Split, and the current micro-frame as indicated by *USB.FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. Figure 44-163 illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

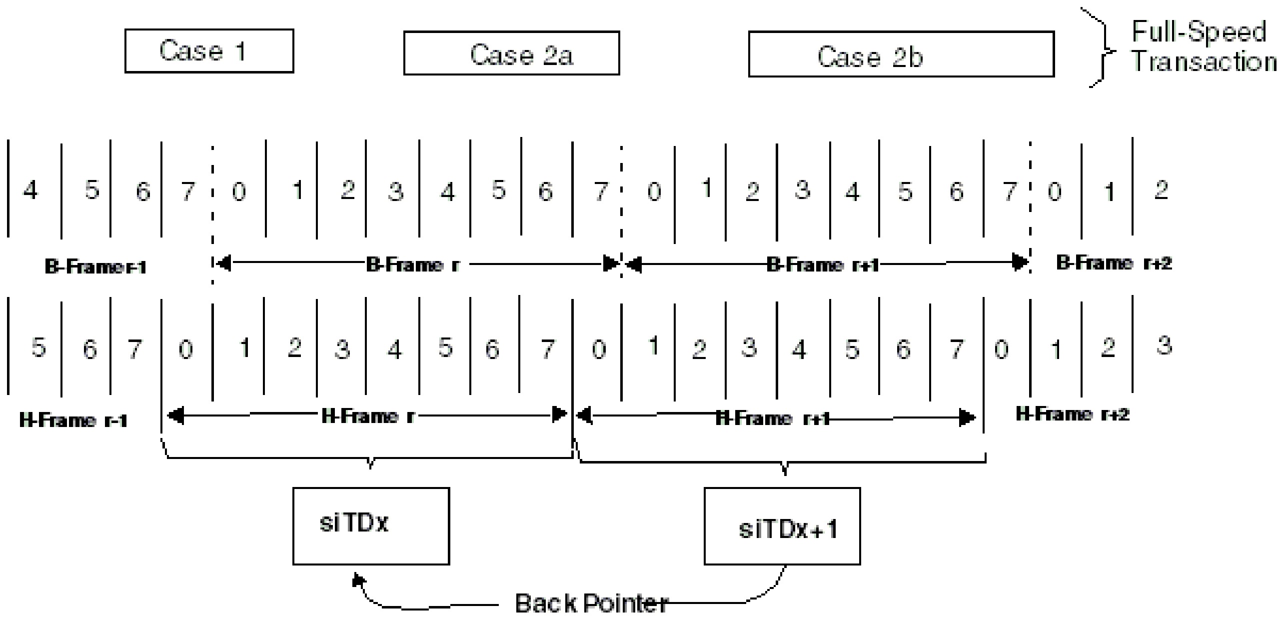

Figure 44-163. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H\text{-}Frame_{Y+1}$, or micro-frame 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic Isochronous - Do Complete Split .

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB

specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

44.6.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB.FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will

respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

44.6.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers , plus the variable *cMicroFrameBit* defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. Figure 44-164 illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

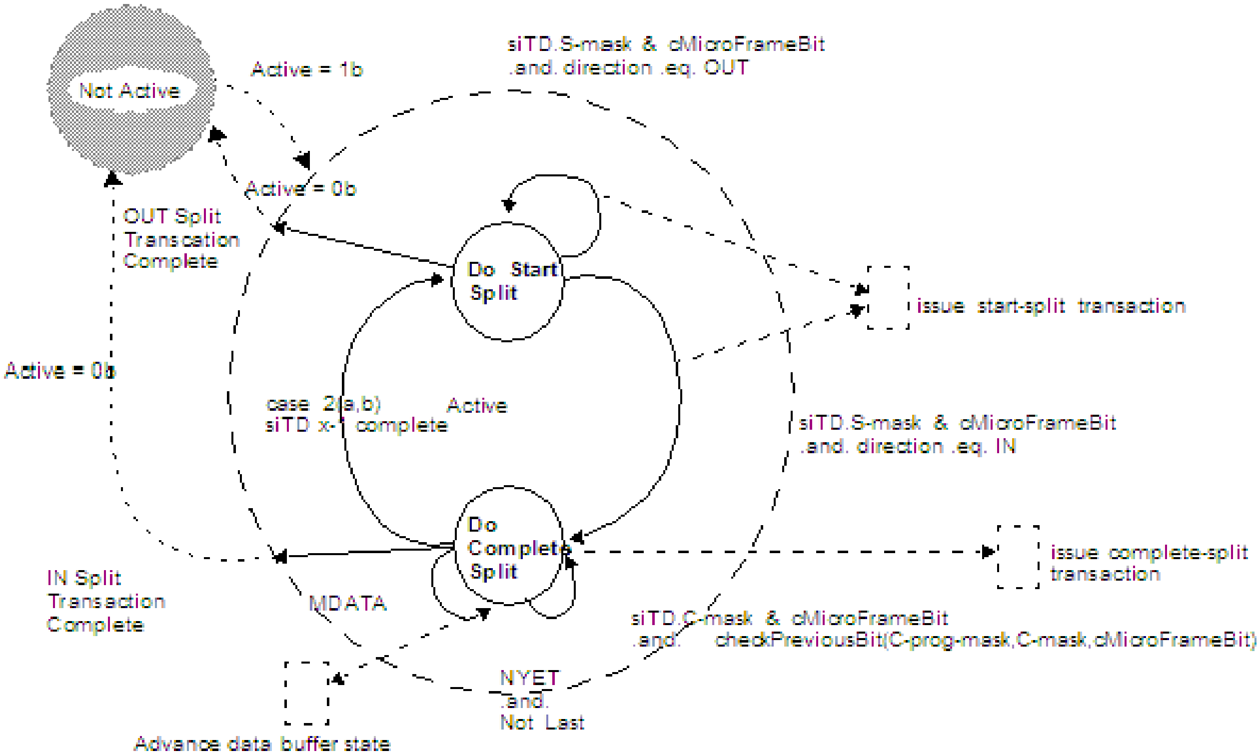

Figure 44-164. Split Transaction State Machine for Isochronous

44.6.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state. An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating *siTD.Current Offset*

with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 44-163) is used to determine the initial value of *TP*. The initial cases are summarized in Table 44-191.

Table 44-191. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

Table 44-192 illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

.

Table 44-192. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 44-192.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split Transaction for Isochronous - Processing Examples .

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Section Periodic Isochronous - Do Complete Split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

44.6.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous - Do Complete Split). The sequence in which this test is applied depends on the current value of USB.FRINDEX[2:0]. If USB.FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous micro-frame. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                               rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and USB.FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 44-162). See Section Periodic Isochronous - Do Complete Split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous - Do Complete Split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

44.6.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 44-162) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. Table 44-193 enumerates the transaction state fields.

Table 44-193. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_{X}$*.Back Pointer*.

The host controller must save the entire state from $siTD_{X}$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 44-193) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_{X}$, and follows its next pointer to the next schedule item. No updates to $siTD_{X}$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$*'sActive* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_{X}$*'s* back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$*'s* complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_{X}$ and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and $siTD_{X}$*.S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_{X}$, then follows $siTD_{X}$*.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_{X}$*.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns

to the context of *siTD*$_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

44.6.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines. The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 44-155).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, Table 44-194 illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 44-194. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, sofware ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic Isochronous - Do Complete Split), that is, before all the scheduled complete-splits have been executed, the host controller will transition *$siTD_X$.SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses its next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it

reaches micro-frame 4. <TBD describe how software detects that there was missing micro-frames (don't think we care about missing out micro-frames. There is enough residual state to identify than not all transactions were executed.).

44.6.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports. When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create ARM platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the ARM platform, based on recent history usage. In the more aggressive power saving modes, the ARM platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the ARM platform power management software can detect this activity over time and inhibit the transition of the ARM platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the ARM platform power management software from placing the ARM platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the ARM platform power management to get the ARM platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the ARM platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the ARM platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

44.6.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0. The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB.CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB.PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

44.6.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources. There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),

- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section Interrupt Enable Register (USB_USBINTR)). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host System Error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, ARM platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section Interrupt Enable Register (USB_USBINTR)) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section USB Status Register (USB_USBSTS)) from a one to a zero.

44.6.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

44.6.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully. Table 44-195 lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 44-195. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Halting a Queue Head .
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

44.6.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*. When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a

queue head (see Halting a Queue Head). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB.USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB.USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

44.6.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction. This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect

the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

44.6.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB.USBSTS register to be set to a one. In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB.USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB.USBSTS register is also set to a one.

44.6.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB.USBSTS register is set to a one. If the *USB Interrupt Enable* bit is set in the USB.USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

44.6.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

44.6.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one. If the *Port Change Interrupt Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

44.6.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs. If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

44.6.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register. If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupton Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule .

44.6.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors. The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. Table 44-196 summarizes the required actions taken on the various host errors.

Table 44-196. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCReset* in the USB.USBCMD register before re-initializing and restarting the host controller.

44.6.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specificationEnhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary. The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

44.6.4.1 Embedded Transaction Translator Function

The USB-HS OTG High-Speed USB On-The-Go OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction trasnslator. Although there is no separate Tranaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator fuction is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

44.6.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

44.6.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the Port Status & Control (USB_PORTSC1) register.

44.6.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in Table 44-197.

Table 44-197. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

44.6.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with an embedded Transaction Translator. Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
    - Hub Address = 0
    - Transactions to direct attached device/hub.
        - QH.EPS = Port Speed
    - Transactions to a device downstream from direct attached FS hub.
        - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

44.6.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specificationUniversal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

44.6.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

44.6.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. Table 44-198 summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 44-198. Summary of the Conditons of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

44.6.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

44.6.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

44.6.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

44.6.4.1.5.3.3 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

44.6.4.1.5.3.4 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

44.6.4.1.5.3.5 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

44.6.4.1.5.3.6 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the Host Controller Structural Parameters (USB_HCSPARAMS) register.

44.6.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

44.6.4.3 USB.USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB Device Mode (USB_USBMODE) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

44.6.4.3.1 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

44.6.4.3.2 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode. EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB Status Register (USB_USBSTS) and Interrupt Enable Register (USB_USBINTR) registers.

44.6.4.4 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

44.6.4.4.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

44.6.4.5 Miscellaneous variations from EHCI

44.6.4.5.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the Port Status & Control (USB_PORTSC1) register providing a capability that is not defined by EHCI.

44.6.4.5.2 Discovery

44.6.4.5.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the Port Status & Control (USB_PORTSC1) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to the reset the controller.
- After 10 ms, software shall write a '0' to the reset the controller.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

44.6.4.5.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.

- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

44.6.4.5.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI since the release of revision 3.2.1. In earlier product revisions, the test packet mode was not EHCI compatible. An alternate host controller driver procedure is no longer necessary or supported.

44.6.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller. The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writeable fields. The device controller must preserve the read-only fields on all data structure writes.

The USB-HS OTG High-Speed USB On-The-Go core includes DCD Software called the USB 2.0 Device API. The Device API provides an easy to use Application Program Interface for developing device (peripheral) applications using the USB-HS OTG High-Speed USB On-The-Go core. The Device API incorporates and abstracts for the application developer all of the elements of the program interface.

Figure 44-165 shows the organization of the End Point Queue Head.

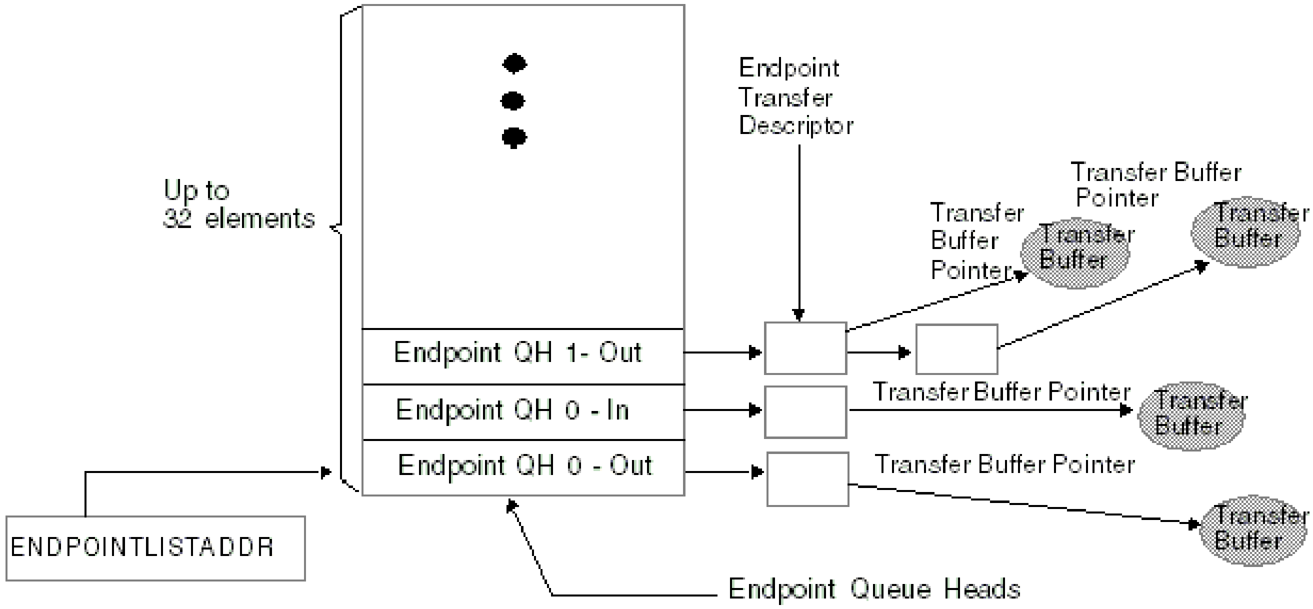

Figure 44-165. End Point Queue Head Organization

Device queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

44.6.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 44-199. Endpoint Queue Head (dQH)

44.6.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 44-200 describes the endpoint capabilities.

Table 44-200. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE:** Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.

Table continues on the next page...

Table 44-200. Endpoint Capabilities/Characteristics (continued)

29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

44.6.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

44.6.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

Table 44-201 describes the dTD Pointer.

Table 44-201. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

44.6.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

Table 44-202 describes the Multiple Mode Control.

Table 44-202. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

44.6.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/ received for given transfer. The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 44-203. Endpoint Transfer Descriptor (dTD)

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td><td></td></tr>

<tr><td colspan="20">Buffer Pointer (Page 4)</td><td colspan="12">Reserved</td><td></td></tr>
</table>

	Device Controller Read/Write		Device Controller Read Only.

Table 44-204 describes the dTD Pointer.

Table 44-204. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

Table 44-205 describes the dTD Token.

Table 44-205. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K(5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K(4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO="00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4,2,0 Reserved.

Table 44-206 describes the dTD Buffer Page Pointer List.

Table 44-206. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

44.6.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus. Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

44.6.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

1. Set Controller Mode in the USBx_USBMODE register to device mode.
2. Allocate and Initialize device queue heads in system memory.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USBx_USBMODE.

- Minimum: Initialize device queue heads 0 Tx & 0 Rx.
- For information on device queue heads, refer to section Device Data Structures.

NOTE

All device queue heads associated with control endpoints must be initialized before the control endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

3. Configure USB.ENDPOINTLISTADDR Pointer.
    - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
4. Enable the microprocessor interrupt associated with the USB-HS OTG High-Speed USB On-The-Go core.
    - Recommended: enable all device interrupts including: USBINT, USBERRINT, USB Reset Received, DCSuspend.
    - For a list of available interrupts refer to the Interrupt Enable Register (USB_USBINTR) and the USB Status Register (USB_USBSTS) register tables.
5. Set Run/Stop bit to Run Mode.
    - After the Run bit is set, a device reset will occur. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the following Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

44.6.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'. After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0. The following state diagram depicts the state of a USB 2.0 device.

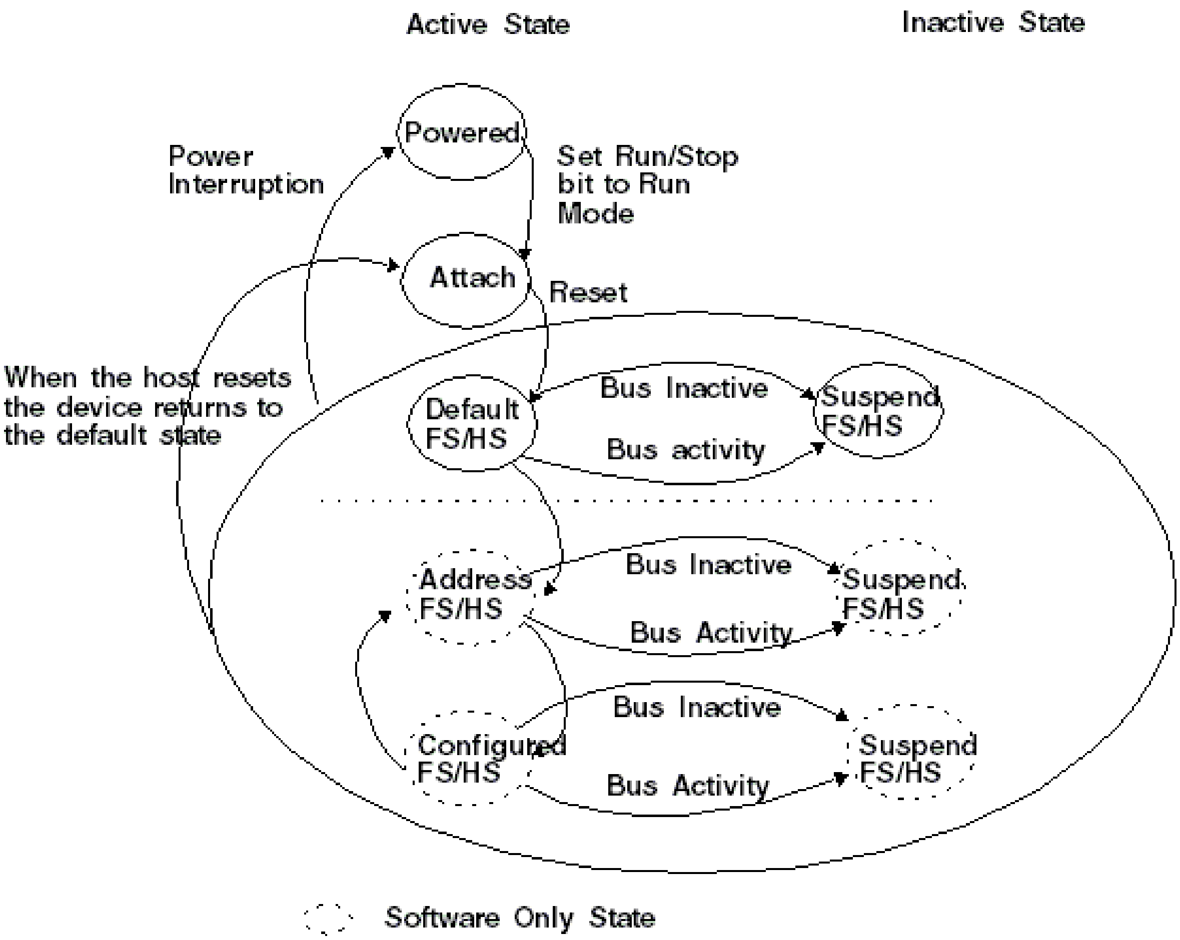

Figure 44-166. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

Table 44-207 describes the Device Controller State Information Bits.

Table 44-207. Device Controller State Information Bits

Bit	Register
DCSuspend	USB Status Register (USB_USBSTS)
USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	Port Status & Control (USB_PORTSC1)

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRLx registers and initializing the associated queue heads.

44.6.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices. When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the Endpoint Status (USB_ENDPTSTAT) register and writing the same value back to the Endpoint Status (USB_ENDPTSTAT) register.

Clear all the endpoint complete status bits by reading the Endpoint Complete (USB_ENDPTCOMPLETE) register and writing the same value back to the Endpoint Complete (USB_ENDPTCOMPLETE) register.

Cancel all primed status by waiting until all bits in the Endpoint Initialization (USB_ENDPTPRIME) are 0 and then writing 0xFFFFFFFF to Endpoint De-Initialize (USB_ENDPTFLUSH).

Read the reset bit in the Port Status & Control (USB_PORTSC1) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the Port Status & Control (USB_PORTSC1) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

44.6.6.2.2 Suspend/Resume

44.6.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the Port Status & Control (USB_PORTSC1) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

44.6.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port. Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the Port Status & Control (USB_PORTSC1) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

44.6.6.2.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that

control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. If the maximum of 16 endpoint numbers, one for each endpoint direction are being used by the device controller, then 32 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

44.6.6.2.4 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRLx register. Each 32-bit ENDPTCTRLx is split into an upper and lower half. The lower half of ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. Table 44-208 shows the fields and values for the Device Controller Endpoint initialization.

Table 44-208. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

44.6.6.2.5 Stalling

There are two occasions where the device controller may need to return to the host a STALL

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRLx register associated with the given endpoint and the given direction. In

a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

Table 44-209 shows the response matrix for the Device Controller Stall.

Table 44-209. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

44.6.6.2.6 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe. For more information on data toggle, refer to the USB 2.0 specification.

44.6.6.2.6.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the ENDPTCTRLx register. This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

44.6.6.2.6.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

44.6.6.2.6.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB.ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

44.6.6.2.6.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

44.6.6.3 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification. At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

44.6.6.3.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 44-210. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

Table 44-211. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

44.6.6.3.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

Table 44-212 shows the response matrix for Interrput/Bulk Endpoint Bus.

Table 44-212. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

44.6.6.3.2 Control Endpoint Operation Model

44.6.6.3.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

In hardware versions 2.3 and later, the setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

Setup Packet Handling (Pre-2.3 hardware)

- After receiving an interrupt and inspecting USB Device Mode (USB_USBMODE) to determine that a setup packet was received on a particular pipe:

1. Duplicate contents of dQH.SsetupBuffer into local software byte array.
2. Write '1' to clear corresponding Endpoint Setup Status (USB_ENDPTSETUPSTAT) bit and thereby disabling Setup Lockout. (That is, the Setup Lockout activates as soon as a setup arrives. By writing to the Endpoint Setup Status (USB_ENDPTSETUPSTAT), the device controller will accept new setup packets.)
3. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

NOTE

To limit the exposure of setup packets to the setup lockout mechanism (if used), the DCD should designate the priority of responding to setup packets above responding to other packet completions.

Setup Packet Handling (2.3 hardware and later)

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB Device Mode (USB_USBMODE). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting Endpoint Setup Status (USB_ENDPTSETUPSTAT) to determine that a setup packet was received on a particular pipe:
  a. Write 1 to clear corresponding bit Endpoint Setup Status (USB_ENDPTSETUPSTAT).
  b. Write 1 to Setup Tripwire (SUTW) in USB Command Register (USB_USBCMD) register.
  c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  d. Read Setup TripWire (SUTW) in USB Command Register (USB_USBCMD) register. (if set - continue; if cleared - goto 2)
  e. Write 0 to clear Setup Tripwire (SUTW) in USB Command Register (USB_USBCMD) register.
  f. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

44.6.6.3.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the Endpoint Initialization (USB_ENDPTPRIME) register is zero and the associated bit in the Endpoint Status (USB_ENDPTSTAT) register is a one. If a prime fails, ie. The Endpoint Initialization (USB_ENDPTPRIME) bit goes to zero and the Endpoint Status (USB_ENDPTSTAT) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (Endpoint Status (USB_ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

44.6.6.3.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

44.6.6.3.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

Table 44-213 shows the response matrix for the Control Endpoint Bus.

Table 44-213. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	

Table continues on the next page...

Table 44-213. Control Endpoint Bus Response Matrix (continued)

Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

44.6.6.3.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes. Real time delivery by the device controller will is accomplished by the following:

- Exactly MULT Packets per (micro)Frame are transmitted/received. Note: MULT is a 2-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets and sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to

the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
    - MULT counter reaches zero.
    - Fulfillment Error [*Transaction Error* bit is set]
        - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
    - MULT counter reaches zero.
    - Non-MDATA Data PID is received**
        - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
    - Overflow Error:
        - Packet received is > maximum packet length. [*Buffer Error* bit is set]
        - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]

- Fulfillment Error [*Transaction Error* bit is set]
  - # Packets Occurred > 0 AND # Packets Occurred < MULT
- CRC Error [*Transaction Error* bit is set

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

44.6.6.3.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochroous data pipe to the host, the (micro)frame number (USB.FRINDEX register) can be used as a marker. To cause a packet transfer to occur at a specific (micro)frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB.FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro)frame N-1 so that the device controller will execute delivery during (micro)frame N.

NOTE

Priming an endpoint towards the end of (micro)frame N-1 will not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

44.6.6.3.3.2 Isochronous Endpoint Bus Response Matrix

Table 44-214 shows the response matrix for the Isochronous Endpoint Bus.

Table 44-214. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

44.6.6.4 Managing Queue Heads

Figure 44-167 shows the End Point Queue Head.

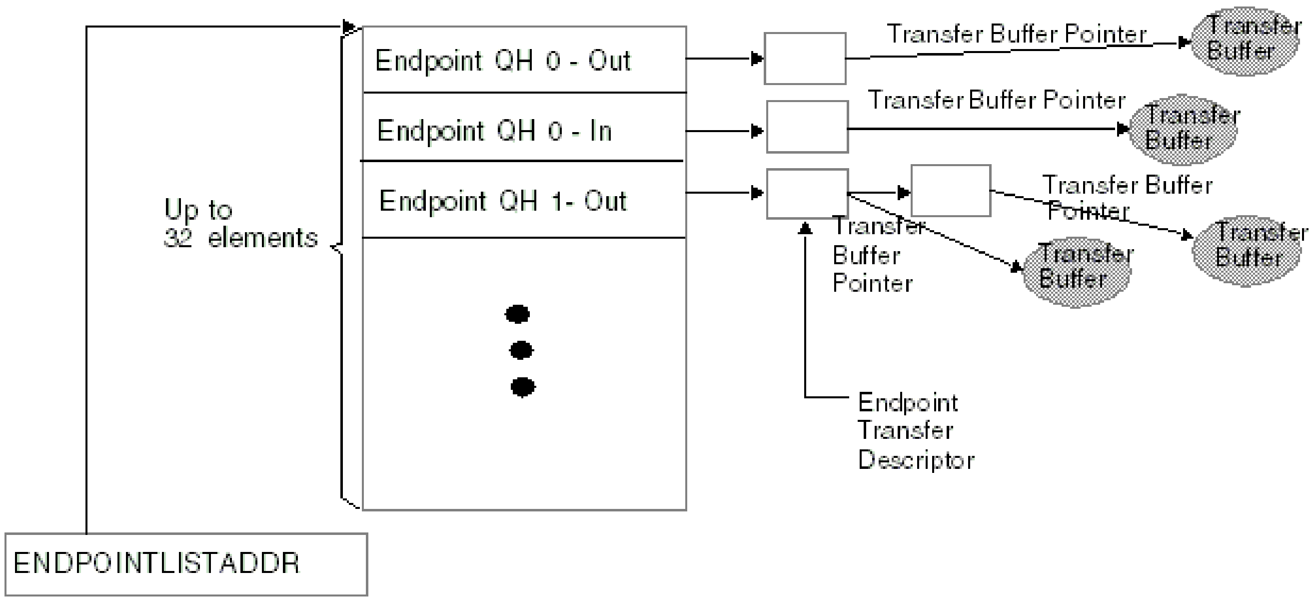

Figure 44-167. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 44-167. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

44.6.6.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required bandwidth an in conjuction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

44.6.6.4.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.

4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

44.6.6.5 Managing Transfers with Transfer Descriptors

44.6.6.5.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. Figure 44-168 shows the Software Link Pointers.

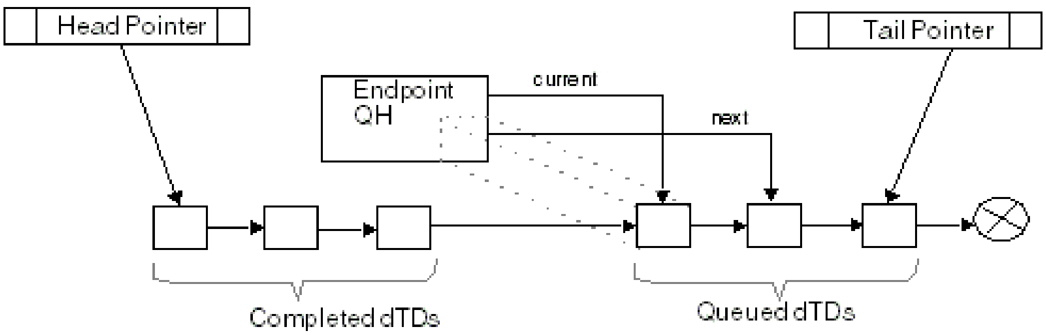

Figure 44-168. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

44.6.6.5.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

44.6.6.5.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty:

- Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding)
- Case 1: Link list is empty
  - 1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  - 2. Clear active & halt bit in dQH (in case set from a previous error).
  - 3. Prime endpoint by writing 1 to correct bit position in Endpoint Initialization (USB_ENDPTPRIME).
- Case 2: Link list is not empty
  - 1. Add dTD to end of linked list.
  - 2. Read correct prime bit in Endpoint Initialization (USB_ENDPTPRIME)- if 1 DONE.
  - 3. Set ATDTW bit in USBCMD register to 1.
  - 4. Read correct status bit in Endpoint Status (USB_ENDPTSTAT). (store in tmp. variable for later)
  - 5. Read ATDTW bit in USBCMD register.
  - If 0 goto 3.
  - If 1 continue to 6.
  - 6. Write ATDTW bit in USBCMD register to 0.

- 7. If status bit read in (3) is 1 DONE.
- 8. If status bit read in (3) is 0 then Goto Case 1: Step 1.

44.6.6.5.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

44.6.6.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in Endpoint De-Initialize (USB_ENDPTFLUSH).
2. Wait until all bits in Endpoint De-Initialize (USB_ENDPTFLUSH) are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read Endpoint Status (USB_ENDPTSTAT) to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using Endpoint De-Initialize (USB_ENDPTFLUSH). A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

44.6.6.5.6 Device Error Matrix

Table 44-215 summarizes packet errors that are not automatically handled by the Device Controller.

Table 44-215. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. Table 44-216 describes the errors.

Table 44-216. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length.
	** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Hst failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

44.6.6.6 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

44.6.6.6.1 High-Frequency Interrupts

High frequency interrupts in particular should be handed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 44-217 describes the High frequency interrupt events.

Table 44-217. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 44-167 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 44-167 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

44.6.6.6.2 Low-Frequency Interrupts

The low frequency events include the following interrupts. These interrupt can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

Table 44-218 shows the Low frequency interrupt events.

Table 44-218. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

44.6.6.6.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

Table 44-219 shows the error interrput events

.

Table 44-219. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

44.7 Glossary of Terms and Abbreviations

This chapter lists and defines terms and abbreviations used throughout this specification.

Table 44-220. Glossary

ACK	Handshake packet indicating a positive acknowledgment.
Active Device	A device that is powered and is not in the Suspend state.
Asynchronous Data	Data transferred at irregular intervals with relaxed latency requirements.
Asynchronous RA	The incoming data rate, $F^{s}i$, and the outgoing data rate, $F^{s}o$, of the RA process are independent (i.e., there is no shared master clock). See also rate adaptation.
Asynchronous SRC	The incoming sample rate, $F^{s}i$, and outgoing sample rate, $F^{s}o$, of the SRC process are independent (i.e., there is no shared master clock). See also sample rate conversion.
Audio Device	A device that sources or sinks sampled analog data.
AWG#	The measurement of a wire's cross-section, as defined by the American Wire Gauge standard.
b/s	Transmission rate expressed in bits per second.
B/s	Transmission rate expressed in bytes per second.
Babble	Unexpected bus activity that persists beyond a specified point in a (micro) frame.
Bandwidth	The amount of data transmitted per unit of time, typically bits per second (b/s) or bytes per second (B/s).
Big Endian	A method of storing data that places the most significant byte of multiple-byte values at a lower storage address. For example, a 16-bit integer stored in big endian format places the least significant byte at the higher address and the most significant byte at the lower address. See also little endian.
Bit	A unit of information used by digital computers. Represents the smallest piece of addressable memory within a computer. A bit expresses the choice between two possibilities and is typically represented by a logical one (1) or zero (0).

Table continues on the next page...

Table 44-220. Glossary (continued)

Bit Stuffing	Insertion of a "0" bit into a data stream to cause an electrical transition on the data wires, allowing a PLL to remain locked.
Buffer	Storage used to compensate for a difference in data rates or time of occurrence of events, when transmitting data from one device to another.
Bulk Transfer	One of the four USB transfer types. Bulk transfers are non-periodic, large burst communication typically used for a transfer that can use any available bandwidth and can be delayed until bandwidth is available. See also transfer type.
Bus Enumeration	Detecting and identifying USB devices.
Byte	A data element that is eight bits in size.
Capabilities	Those attributes of a USB device that are administrated by the host.
Characteristics	Those qualities of a USB device that are unchangeable; for example, the device class is a device characteristic.
Client	Software resident on the host that interacts with the USB System Software to arrange data transfer between a function and the host. The client is often the data provider and consumer for transferred data.
Configuring Software	Software resident on the host software that is responsible for configuring a USB device. This may be a system configurator or software specific to the device.
Control Endpoint	A pair of device endpoints with the same endpoint number that are used by a control pipe. Control endpoints transfer data in both directions and, therefore, use both endpoint directions of a device address and endpoint number combination. Thus, each control endpoint consumes two endpoint addresses.
Control Pipe	Same as a message pipe.
Control Transfer	One of the four USB transfer types. Control transfers support configuration/command/status type communications between client and function. See also transfer type.
CRC	See Cyclic Redundancy Check.
CTI	Computer Telephony Integration.
Cyclic Redundancy Check (CRC)	A check performed on data to see if an error has occurred in transmitting, reading, or writing the data. The result of a CRC is typically stored or transmitted with the checked data. The stored or transmitted result is compared to a CRC calculated for the data to determine if an error has occurred.
Default Address	An address defined by the USB Specification and used by a USB device when it is first powered or reset. The default address is 00H.
Default Pipe	The message pipe created by the USB System Software to pass control and status information between the host and a USB device's endpoint zero.
Device	A logical or physical entity that performs a function. The actual entity described depends on the context of the reference. At the lowest level, device may refer to a single hardware component, as in a memory device. At a higher level, it may refer to a collection of hardware components that perform a particular function, such as a USB interface device. At an even higher level, device may refer to the function performed by an entity attached to the USB; for example, a data/FAX modem device. Devices may be physical, electrical, addressable, and logical. When used as a non-specific reference, a USB device is either a hub or a function.
Device Address	A seven-bit value representing the address of a device on the USB. The device address is the default address (00H) when the USB device is first powered or the device is reset. Devices are assigned a unique device address by the USB System Software.
Device Endpoint	A uniquely addressable portion of a USB device that is the source or sink of information in a communication flow between the host and device. See also endpoint address.
Device Resources	Resources provided by USB devices, such as buffer space and endpoints. See also Host Resources and Universal Serial Bus Resources.

Table continues on the next page...

Table 44-220. Glossary (continued)

Device Software	Software that is responsible for using a USB device. This software may or may not also be responsible for configuring the device for use.
Downstream	The direction of data flow from the host or away from the host. A downstream port is the port on a hub electrically farthest from the host that generates downstream data traffic from the hub. Downstream ports receive upstream data traffic.
Driver	When referring to hardware, an I/O pad that drives an external load. When referring to software, a program responsible for interfacing to a hardware device, that is, a device driver.
DWord	Double word. A data element that is two words (i.e., four bytes or 32 bits) in size.
Dynamic Insertion and Removal	The ability to attach and remove devices while the host is in operation.
E^2PROM	See Electrically Erasable Programmable Read Only Memory.
EEPROM	See Electrically Erasable Programmable Read Only Memory.
Electrically Erasable Programmable Read Only Memory (EEPROM)	Non-volatile rewriteable memory storage technology.
End User	The user of a host.
Endpoint	See device endpoint.
Endpoint Address	The combination of an endpoint number and an endpoint direction on a USB device. Each endpoint address supports data transfer in one direction.
Endpoint Direction	The direction of data transfer on the USB. The direction can be either IN or OUT. IN refers to transfers to the host; OUT refers to transfers from the host.
Endpoint Number	A four-bit value between 0H and FH, inclusive, associated with an endpoint on a USB device.
Envelope detector	An electronic circuit inside a USB device that monitors the USB data lines and detects certain voltage related signal characteristics.
EOF	End-of- (micro) Frame.
EOP	End-of-Packet.
External Port	See port.
Eye pattern	A representation of USB signaling that provides minimum and maximum voltage levels as well as signal jitter.
False EOP	A spurious, usually noise-induced event that is interpreted by a packet receiver as an EOP.
Flush (Endpoint)	A term used in this device controller implementation to describe the action of clearing an endpoint ready status.
Frame	A 1-millisecond time base established on full-/low-speed buses.
Frame Pattern	A sequence of frames that exhibit a repeating pattern in the number of samples transmitted per frame. For a 44.1 kHz audio transfer, the frame pattern could be nine frames containing 44 samples followed by one-frame containing45 samples.
Fs	See sample rate.
Full-duplex	Computer data transmission occurring in both directions simultaneously.
Full-speed	USB operation at 12 Mb/s. See also low-speed and high-speed
Function	A USB device that provides a capability to the host, such as an ISDN connection, a digital microphone, or speakers.
Handshake Packet	A packet that acknowledges or rejects a specific condition. For examples, see ACK and NAK.
High-bandwidth endpoint	A high-speed device endpoint that transfers more than 1024 bytes and less than3073 bytes per microframe.
High-speed	USB operation at 480 Mb/s. See also low-speed and full-speed

Table continues on the next page...

Table 44-220. Glossary (continued)

Host	The host computer system where the USB Host Controller is installed. This includes the host hardware platform (CPU, bus, etc.) and the operating system in use.
Host Controller	The host's USB interface.
Host Controller Driver (HCD)	The USB software layer that abstracts the Host Controller hardware. The Host Controller Driver provides an SPI for interaction with a Host Controller. The Host Controller Driver hides the specifics of the Host Controller hardware implementation.
Host Resources	Resources provided by the host, such as buffer space and interrupts. See also Device Resources and Universal Serial Bus Resources.
Hub	A USB device that provides additional connections to the USB.
Hub Tier	One plus the number of USB links in a communication path between the host and a function.
I/O Request Packet	An identifiable request by a software client to move data between itself (on the host) and an endpoint of a device in an appropriate direction.
Interrupt Request (IRQ)	A hardware signal that allows a device to request attention from a host. The host typically invokes an interrupt service routine to handle the condition that caused the request.
Interrupt Transfer	One of the four USB transfer types. Interrupt transfer characteristics are small data, non-periodic, low frequency, and bounded-latency. Interrupt transfers are typically used to handle service needs. See also transfer type.
IRP	See I/O Request Packet.
IRQ	See Interrupt Request.
Isochronous Data	A stream of data whose timing is implied by its delivery rate
Isochronous Device	An entity with isochronous endpoints, as defined in the USB Specification, that sources or sinks sampled analog streams or synchronous data streams.
Isochronous Sink Endpoint	An endpoint that is capable of consuming an isochronous data stream that is sent by the host.
Isochronous Source Endpoint	An endpoint that is capable of producing an isochronous data stream and sending it to the host.
Isochronous Transfer	One of the four USB transfer types. Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device. See also transfer type.
Jitter	A tendency toward lack of synchronization caused by mechanical or electrical changes. More specifically, the phase shift of digital pulses over a transmission medium.
kb/s	Transmission rate expressed in kilobits per second.
kB/s	Transmission rate expressed in kilobytes per second.
Little Endian	Method of storing data that places the least significant byte of multiple-byte values at lower storage addresses. For example, a 16-bit integer stored in little endian format places the least significant byte at the lower address and the most significant byte at the next address. See also big endian.
LOA	Loss of bus activity characterized by an SOP without a corresponding EOP.
Low-speed	USB operation at 1.5 Mb/s. See also full-speed and high-speed.
LSb	Least significant bit.
LSB	Least significant byte.
Mb/s	Transmission rate expressed in megabits per second.
MB/s	Transmission rate expressed in megabytes per second.
Message Pipe	A bi-directional pipe that transfers data using a request/data/status paradigm. The data has an imposed structure that allows requests to be reliably identified and communicated.
Microframe	A 125-microsecond time base established on high-speed buses.

Table continues on the next page...

Table 44-220. Glossary (continued)

MSb	Most significant bit.
MSB	Most significant byte.
NAK	Handshake packet indicating a negative acknowledgment.
Non Return to Zero Invert (NRZI)	A method of encoding serial data in which ones and zeroes are represented by opposite and alternating high and low voltages where there is no return to zero (reference) voltage between encoded bits. Eliminates the need for clock pulses.
NRZI	See Non Return to Zero Invert.
Object	Host software or data structure representing a USB entity.
Packet	A bundle of data organized in a group for transmission. Packets typically contain three elements: control information (e.g., source, destination, and length), the data to be transferred, and error detection and correction bits.
Packet Buffer	The logical buffer used by a USB device for sending or receiving a single packet. This determines the maximum packet size the device can send or receive.
Packet ID (PID)	A field in a USB packet that indicates the type of packet and by inference, the format of the packet and the type of error detection applied to the packet.
PCI	Programming and control interface
Phase	A token, data, or handshake packet. A transaction has three phases
Phase Locked Loop (PLL)	A circuit that acts as a phase detector to keep an oscillator in phase with an incoming frequency.
Physical Device	A device that has a physical implementation; e.g., speakers, microphones, and CD players.
PID	See Packet ID.
Pipe	A logical abstraction representing the association between an endpoint on a device and software on the host. A pipe has several attributes; for example, a pipe may transfer data as streams (stream pipe) or messages (message pipe) See also stream pipe and message pipe.
PLL	See Phase Locked Loop.
Polling	Asking multiple devices, one at a time, if they have any data to transmit.
POR	See Power On Reset.
Port	Point of access to or from a system or circuit. For the USB, the point where a USB device is attached.
Power On Reset (POR)	Restoring a storage device, register, or memory to a predetermined state when power is applied.
Prime (Endpoint)	A term used in this device controller implementation to describe the action of readying an endpoint to transmit or receive data.
Programmable Data Rate	A fixed data rate (single-frequency endpoints), a limited number of data rates (32 kHz, 44.1 kHz, 48 kHz, …), or a continuously programmable data rate. The exact programming capabilities of an endpoint must be reported in the appropriate class-specific endpoint descriptors.
Protocol	A specific set of rules, procedures, or conventions relating to format and timing of data transmission between two devices.
RA	See rate adaptation.
Rate Adaptation	The process by which an incoming data stream, sampled at $F^{s}i$, is converted to an outgoing data stream, sampled at $F^{s}o$, with a certain loss of quality, determined by the rate adaptation algorithm. Error control mechanisms are required for the process. $F^{s}i$ and $F^{s}o$ can be different and asynchronous. $F^{s}i$ is the input data rate of the RA; $F^{s}o$ is the output data rate of the RA.
Request	A request made to a USB device contained within the data portion of a SETUP packet.
Retire	The action of completing service for a transfer and notifying the appropriate software client of the completion.
Root Hub	A USB hub directly attached to the Host Controller. This hub (tier 1) is attached to the host.

Table continues on the next page...

Table 44-220. Glossary (continued)

Root Port	The downstream port on a Root Hub.
Sample	The smallest unit of data on which an endpoint operates; a property of an endpoint.
Sample Rate (Fs)	The number of samples per second, expressed in Hertz (Hz).
Sample Rate Conversion (SRC)	A dedicated implementation of the RA process for use on sampled analog data streams. The error control mechanism is replaced by interpolating techniques.
Service	A procedure provided by a System Programming Interface (SPI).
Service Interval	The period between consecutive requests to a USB endpoint to send or receive data.
Service Jitter	The deviation of service delivery from its scheduled delivery time.
Service Rate	The number of services to a given endpoint per unit time.
SOF	See Start-of-Frame.
SOP	Start-of-Packet.
SPI	See System Programming Interface.
Split transaction	A transaction type supported by host controllers and hubs. This transaction type allows full- and low-speed devices to be attached to hubs operating at high-speed.
SRC	See Sample Rate Conversion.
Stage	One part of the sequence composing a control transfer; stages include the Setup stage, the Data stage, and the Status stage.
Start-of-Frame (SOF)	The first transaction in each (micro) frame. An SOF allows endpoints to identify the start of the (micro) frame and synchronize internal endpoint clocks to the host.
Stream Pipe	A pipe that transfers data as a stream of samples with no defined USB structure.
Synchronization Type	A classification that characterizes an isochronous endpoint's capability to connect to other isochronous endpoints.
Synchronous RA	The incoming data rate, F^si, and the outgoing data rate, F^so, of the RA process, are derived from the same master clock. There is a fixed relation between F^si and F^so.
Synchronous SRC	The incoming sample rate, F^si, and outgoing sample rate, F^so, of the SRC process are derived from the same master clock. There is a fixed relation between F^si and F^so.
System Programming Interface (SPI)	A defined interface to services provided by system software.
TDM	See Time Division Multiplexing.
TDR	See Time Domain Reflectometer.
Termination	Passive components attached at the end of cables to prevent signals from being reflected or echoed.
Time Division Multiplexing (TDM)	A method of transmitting multiple signals (data, voice, and/or video) simultaneously over one communications medium by interleaving a piece of each signal one after another.
Time Domain Reflectometer (TDR)	An instrument capable of measuring impedance characteristics of the USB signal lines.
Timeout	The detection of a lack of bus activity for some predetermined interval.
Token Packet	A type of packet that identifies what transaction is to be performed on the bus.
Transaction	The delivery of service to an endpoint; consists of a token packet, optional data packet, and optional handshake packet. Specific packets are allowed/required based on the transaction type.
Companion Controller	A functional component of a USB hub. The Companion Controller responds to special high-speed transactions and translates them to full/low-speed transactions with full/low-speed devices attached on downstream facing ports.
Transfer	One or more bus transactions to move information between a software client and its function.

Table continues on the next page...

Table 44-220. Glossary (continued)

Transfer Type	Determines the characteristics of the data flow between a software client and its function. Four standard transfer types are defined: control, interrupt, bulk, and isochronous.
Turn-around Time	The time a device needs to wait to begin transmitting a packet after a packet has been received to prevent collisions on the USB. This time is based on the length and propagation delay characteristics of the cable and the location of the transmitting device in relation to other devices on the USB.
Universal Serial Bus Driver (USBD)	The host resident software entity responsible for providing common services to clients that are manipulating one or more functions on one or more Host Controllers.
Universal Serial Bus Resources	Resources provided by the USB, such as bandwidth and power. See also Device Resources and Host Resources.
Upstream	The direction of data flow towards the host. An upstream port is the port on a device electrically closest to the host that generates upstream data traffic from the hub. Upstream ports receive downstream data traffic.
USBD	See Universal Serial Bus Driver.
USB-IF	USB Implementers Forum, Inc. is a nonprofit corporation formed to facilitate the development of USB compliant products and promote the technology.
Virtual Device	A device that is represented by a software interface layer. An example of a virtual device is a hard disk with its associated device driver and client software that makes it able to reproduce an audio .WAV file.
Word	A data element that is two bytes (16 bits) in size.

Chapter 45
Universal Serial Bus 2.0 Integrated PHY (USBPHY)

45.1 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s. See the following figure for a block diagram of the PHY.

The integrated PHY provides a standard UTM interface. The USB_DP and USB_DM pins connect directly to a USB connector. USBPHY0 is the PHY interface for USB OTG 0 controller; USBPHY1 is the PHY interface for USB OTG 1 controller.

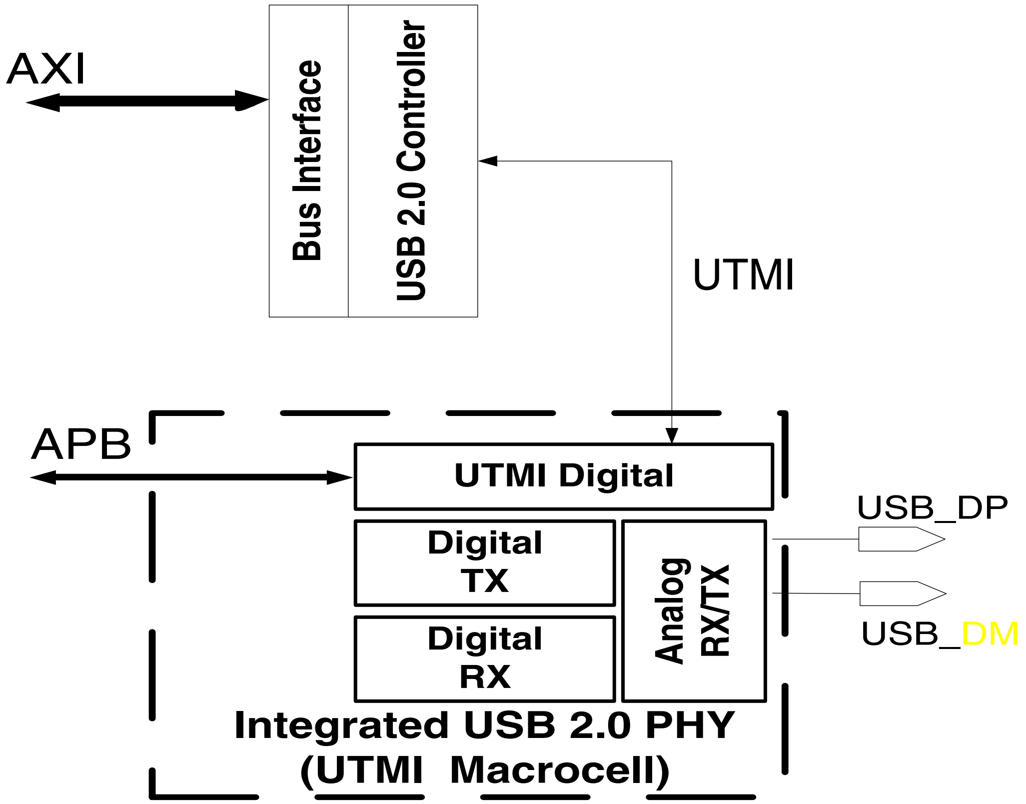

Figure 45-1. USB 2.0 PHY Block Diagram

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.

45.2 USB PHY Memory Map/Register Definition

USBPHY Hardware Register Format Summary

USBPHY0 base address is 0x 4005_ 0800; USBPHY1 base address is 0x 4005_ 0C00

USBPHY memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_0800	USB PHY Power-Down Register (USBPHY0_PWD)	32	R/W	001E_1C00h	45.2.1/2375

Table continues on the next page...

USBPHY memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_0804	USB PHY Power-Down Register (USBPHY0_PWD_SET)	32	R/W	001E_1C00h	45.2.1/2375
4005_0808	USB PHY Power-Down Register (USBPHY0_PWD_CLR)	32	R/W	001E_1C00h	45.2.1/2375
4005_080C	USB PHY Power-Down Register (USBPHY0_PWD_TOG)	32	R/W	001E_1C00h	45.2.1/2375
4005_0810	USB PHY Transmitter Control Register (USBPHY0_TX)	32	R/W	1006_0607h	45.2.2/2377
4005_0820	USB PHY Receiver Control Register (USBPHY0_RX)	32	R/W	0000_0000h	45.2.3/2378
4005_0824	USB PHY Receiver Control Register (USBPHY0_RX_SET)	32	R/W	0000_0000h	45.2.3/2378
4005_0828	USB PHY Receiver Control Register (USBPHY0_RX_CLR)	32	R/W	0000_0000h	45.2.3/2378
4005_082C	USB PHY Receiver Control Register (USBPHY0_RX_TOG)	32	R/W	0000_0000h	45.2.3/2378
4005_0830	USB PHY General Control Register (USBPHY0_CTRL)	32	R/W	C020_0040h	45.2.4/2380
4005_0834	USB PHY General Control Register (USBPHY0_CTRL_SET)	32	R/W	C020_0040h	45.2.4/2380
4005_0838	USB PHY General Control Register (USBPHY0_CTRL_CLR)	32	R/W	C020_0040h	45.2.4/2380
4005_083C	USB PHY General Control Register (USBPHY0_CTRL_TOG)	32	R/W	C020_0040h	45.2.4/2380
4005_0840	USB PHY Status Register (USBPHY0_STATUS)	32	R/W	0000_0000h	45.2.5/2383
4005_0850	USB PHY Debug Register (USBPHY0_DEBUG)	32	R/W	7F18_0000h	45.2.6/2385
4005_0854	USB PHY Debug Register (USBPHY0_DEBUG_SET)	32	R/W	7F18_0000h	45.2.6/2385
4005_0858	USB PHY Debug Register (USBPHY0_DEBUG_CLR)	32	R/W	7F18_0000h	45.2.6/2385
4005_085C	USB PHY Debug Register (USBPHY0_DEBUG_TOG)	32	R/W	7F18_0000h	45.2.6/2385
4005_0860	UTMI Debug Status Register 0 (USBPHY0_DEBUG0_STATUS)	32	R	0000_0000h	45.2.7/2387
4005_0870	UTMI Debug Status Register 1 (USBPHY0_DEBUG1)	32	R/W	0000_1000h	45.2.8/2387
4005_0874	UTMI Debug Status Register 1 (USBPHY0_DEBUG1_SET)	32	R/W	0000_1000h	45.2.8/2387
4005_0878	UTMI Debug Status Register 1 (USBPHY0_DEBUG1_CLR)	32	R/W	0000_1000h	45.2.8/2387
4005_087C	UTMI Debug Status Register 1 (USBPHY0_DEBUG1_TOG)	32	R/W	0000_1000h	45.2.8/2387
4005_0880	UTMI RTL Version (USBPHY0_VERSION)	32	R	0402_0000h	45.2.9/2388
4005_0890	USB PHY IP Block Register (USBPHY0_IP)	32	R/W	0000_0000h	45.2.10/ 2389
4005_0894	USB PHY IP Block Register (USBPHY0_IP_SET)	32	R/W	0000_0000h	45.2.10/ 2389
4005_0898	USB PHY IP Block Register (USBPHY0_IP_CLR)	32	R/W	0000_0000h	45.2.10/ 2389
4005_089C	USB PHY IP Block Register (USBPHY0_IP_TOG)	32	R/W	0000_0000h	45.2.10/ 2389
4005_0C00	USB PHY Power-Down Register (USBPHY1_PWD)	32	R/W	001E_1C00h	45.2.1/2375
4005_0C04	USB PHY Power-Down Register (USBPHY1_PWD_SET)	32	R/W	001E_1C00h	45.2.1/2375
4005_0C08	USB PHY Power-Down Register (USBPHY1_PWD_CLR)	32	R/W	001E_1C00h	45.2.1/2375
4005_0C0C	USB PHY Power-Down Register (USBPHY1_PWD_TOG)	32	R/W	001E_1C00h	45.2.1/2375
4005_0C10	USB PHY Transmitter Control Register (USBPHY1_TX)	32	R/W	1006_0607h	45.2.2/2377

4005_0C9C	USB PHY IP Block Register (USBPHY1_IP_TOG)	32	R/W	0000_0000h	45.2.10/ 2389

45.2.1 USB PHY Power-Down Register (USBPHYx_PWD*n*)

The USB PHY Power-Down Register provides overall control of the PHY power state.

Address: Base address + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD2											RXPWDRX	RXPWDDIFF	RXPWD1PT1	RXPWDENV	RSVD1
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1			TXPWDV2I	TXPWDIBIAS	TXPWDFS	RSVD0									
W																
Reset	0	0	0	1	1	1	0	0	0	0	0	0	0	0	0	0

USBPHYx_PWD*n* field descriptions

Field	Description
31–21 RSVD2	Reserved.
20 RXPWDRX	0 = Normal operation. 1 = Power-down the entire USB PHY receiver block except for the full-speed differential receiver. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
19 RXPWDDIFF	0 = Normal operation. 1 = Power-down the USB high-speed differential receiver. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.

Table continues on the next page...

USBPHYx_PWD*n* field descriptions (continued)

Field	Description
18 RXPWD1PT1	0 = Normal operation. 1 = Power-down the USB full-speed differential receiver. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
17 RXPWDENV	0 = Normal operation. 1 = Power-down the USB high-speed receiver envelope detector (squelch signal). Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
16–13 RSVD1	Reserved.
12 TXPWDV2I	This bit is used to powerdown the USB PHY transmit V-to-I converter and the current mirror. **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Nornal operation. 1 Powerdown the USB PHY transmit V-to-I converter and the current mirror.
11 TXPWDIBIAS	This bit can power-down the USB PHY current bias block for the transmitter. **NOTE:** This bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled. 0 Normal operation 1 Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path.
10 TXPWDFS	0 = Normal operation. 1 = Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHY_CTRL is enabled.
9–0 RSVD0	Reserved.

45.2.2 USB PHY Transmitter Control Register (USBPHYx_TX)

The USB PHY Transmitter Control Register handles the transmit controls.

Address: Base address + 10h offset = 4005_0810h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD2												TXCAL45DP				RSVD1				TXCAL45DM				RSVD0				D_CAL			
W																																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	1

USBPHYx_TX field descriptions

Field	Description
31–20 RSVD2	Reserved.
19–16 TXCAL45DP	Decode to trim the nominal 45-Ohm resistance to the USB_DP output pin. Maximum resistance = 0000. Resistance is centered by design at 0110. **NOTE:** Trimming this resistance will impact both the overshoot/undershoot of the Full Speed TX output and the amplitude of the High Speed TX output.
15–12 RSVD1	Reserved. **Note:** This bit should remain clear.
11–8 TXCAL45DM	Decode to trim the nominala 45-Ohm resistance to the USB_DM output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
7–4 RSVD0	Reserved. **Note:** This bit should remain clear.
3–0 D_CAL	Decode to trim the nominal 17.78ma current source for the High Speed TX drivers on USB_DP and USB_DM. This current is directly proportional to the amplitude of the High Speed TX eye diagram.> 0000 Maximum current, approximately 19% above nominal. 0111 Nominal. 1111 Minimum current, approximately 19% below nominal

45.2.3 USB PHY Receiver Control Register (USBPHY*x*_RX*n*)

The USB PHY Receiver Control Register handles receive path controls.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD2									RXDBYPASS	RSVD1					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1									DISCONADJ			RSVD0	ENVADJ		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY*x*_RX*n* field descriptions

Field	Description
31–23 RSVD2	Reserved.
22 RXDBYPASS	0 = Normal operation. 1 = Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver. This test mode is intended for lab use only.

Table continues on the next page...

USBPHYx_RX*n* field descriptions (continued)

Field	Description
21–7 RSVD1	Reserved.
6–4 DISCONADJ	The DISCONADJ field adjusts the trip point for the disconnect detector: 0000 = Trip-Level Voltage is 0.57500 V 0001 = Trip-Level Voltage is 0.56875 V 0010 = Trip-Level Voltage is 0.58125 V 0011 = Trip-Level Voltage is 0.58750 V 01XX = Reserved 1XXX = Reserved
3 RSVD0	Reserved.
2–0 ENVADJ	The ENVADJ field adjusts the trip point for the envelope detector. 000 = Trip-Level Voltage is 0.11250 V 001 = Trip-Level Voltage is 0.10000 V 010 = Trip-Level Voltage is 0.13750 V 011 = Trip-Level Voltage is 0.10625 V 1XX = Reserved

45.2.4 USB PHY General Control Register (USBPHYx_CTRLn)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

Address: Base address + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	ENUTMILEVEL3	ENUTMILEVEL2	DATA_ON_LRADC	DEVPLUGIN_IRQ	ENIRQDEVPLUGIN	RESUME_IRQ	ENIRQRESUMEDETECT	RESUMEIRQSTICKY	ENOTGIDDETECT	OTG_ID_CHG_IRQ	DEVPLUGIN_POLARITY	ENDEVPLUGINDETECT	HOSTDISCONDETECT_IRQ	ENIRQHOSTDISCON	ENHOSTDISCONDETECT	ENOTG_ID_CHG_IRQ
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

USBPHYx_CTRLn field descriptions

Field	Description
31 SFTRST	Writing a 1 to this bit will soft-reset the USBPHY_PWD, USBPHY_TX, USBPHY_RX, and USBPHY_CTRL registers.
30 CLKGATE	Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated. Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHY_CTRL is enabled.
29 UTMI_SUSPENDM	Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHY_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	Forces the next FS packet that is transmitted to have a EOP with LS timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHY_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHY_DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	Almost same as OTGID_STATUS in USBPHY_STATUS Register. The only difference is that OTG_ID_VALUE has debounce logic to filter the glitches on ID Pad.

Table continues on the next page...

USBPHY*x*_CTRL*n* field descriptions (continued)

Field	Description
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 FSDLL_RST_EN	Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 ENVBUSCHG_WKUP	Enables the feature to wakeup USB if VBUS is toggled when USB is suspended.
22 ENIDCHG_WKUP	Enables the feature to wakeup USB if ID is toggled when USB is suspended.
21 ENDPDMCHG_WKUP	Enables the feature to wakeup USB if DP/DM is toggled when USB is suspended. This bit is enabled by default.
20 ENAUTOCLR_PHY_PWD	Enables the feature to auto-clear the PWD register bits in USBPHY_PWD if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
19 ENAUTOCLR_CLKGATE	Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
18 Reserved	This field is reserved.
17 WAKEUP_IRQ	Indicates that there is a wakeup event. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
16 ENIRQWAKEUP	Enables interrupt for the wakeup events.
15 ENUTMILEVEL3	Enables UTMI+ Level3. This should be enabled if needs to support external FS Hub with LS device connected
14 ENUTMILEVEL2	Enables UTMI+ Level2. This should be enabled if needs to support LS device
13 DATA_ON_LRADC	Enables the LRADC to monitor USB_DP and USB_DM. This is for use in non-USB modes only.
12 DEVPLUGIN_IRQ	Indicates that the device is connected. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
11 ENIRQDEVPLUGIN	Enables interrupt for the detection of connectivity to the USB line.
10 RESUME_IRQ	Indicates that the host is sending a wake-up after suspend. This bit is also set on a reset during suspend. Use this bit to wake up from suspend for either the resume or the reset case. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
9 ENIRQRESUMEDETECT	Enables interrupt for detection of a non-J state on the USB line. This should only be enabled after the device has entered suspend mode.
8 RESUMEIRQSTICKY	Set to 1 will make RESUME_IRQ bit a sticky bit until software clear it. Set to 0, RESUME_IRQ only set during the wake-up period.
7 ENOTGIDDETECT	Enables circuit to detect resistance of MiniAB ID pin.

Table continues on the next page...

USBPHY*x*_CTRL*n* field descriptions (continued)

Field	Description
6 OTG_ID_CHG_IRQ	OTG ID change interrupt. Indicates the value of ID pin changed.
5 DEVPLUGIN_POLARITY	For device mode, if this bit is cleared to 0, then it trips the interrupt if the device is plugged in. If set to 1, then it trips the interrupt if the device is unplugged.
4 ENDEVPLUGINDETECT	For device mode, enables 200-KOhm pullups for detecting connectivity to the host.
3 HOSTDISCONDETECT_ IRQ	Indicates that the device has disconnected in high-speed mode. Reset this bit by writing a 1 to the SCT clear address space and not by a general write.
2 ENIRQHOSTDISCON	Enables interrupt for detection of disconnection to Device when in high-speed host mode. This should be enabled after ENDEVPLUGINDETECT is enabled.
1 ENHOSTDISCONDETECT	For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet.
0 ENOTG_ID_CHG_IRQ	Enable OTG_ID_CHG_IRQ.

45.2.5 USB PHY Status Register (USBPHYx_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD4															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD4					RESUME_STATUS	RSVD3	OTGID_STATUS	RSVD2	DEVPLUGIN_STATUS	RSVD1		HOSTDISCONDETECT_STATUS	RSVD0		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx_STATUS field descriptions

Field	Description
31–11 RSVD4	Reserved.
10 RESUME_STATUS	Indicates that the host is sending a wake-up after suspend and has triggered an interrupt.
9 RSVD3	Reserved.
8 OTGID_STATUS	Indicates the results of ID pin on MiniAB plug. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 RSVD2	Reserved.
6 DEVPLUGIN_STATUS	Indicates that the device has been connected on the USB_DP and USB_DM lines.
5–4 RSVD1	Reserved.
3 HOSTDISCONDETECT_ STATUS	Indicates that the device has disconnected while in high-speed host mode.
2–0 RSVD0	Reserved.

45.2.6 USB PHY Debug Register (USBPHYx_DEBUG*n*)

This register is used to debug the USB PHY.

Address: Base address + 50h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD3	CLKGATE	HOST_RESUME_DEBUG	SQUELCHRESETLENGTH				ENSQUELCHRESET	RSVD2			SQUELCHRESETCOUNT				
W																
Reset	0	1	1	1	1	1	1	1	0	0	0	1	1	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1			ENTX2RXCOUNT	TX2RXCOUNT				RSVD0		ENHSTPULLDOWN		HSTPULLDOWN		DEBUG_INTERFACE_HOLD	OTGIDPIOLOCK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx_DEBUGn field descriptions

Field	Description
31 RSVD3	Reserved.
30 CLKGATE	Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28–25 SQUELCHRESETLENGTH	Duration of RESET in terms of the number of 480-MHz cycles.
24 ENSQUELCHRESET	Set bit to allow squelch to reset high-speed receive.
23–21 RSVD2	Reserved.
20–16 SQUELCHRESETCOUNT	Delay in between the detection of squelch to the reset of high-speed RX.
15–13 RSVD1	Reserved.
12 ENTX2RXCOUNT	Set this bit to allow a countdown to transition in between TX and RX.
11–8 TX2RXCOUNT	Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7–6 RSVD0	Reserved.
5–4 ENHSTPULLDOWN	Set bit 5 to 1 to override the control of the USB_DP 15-KOhm pulldown. Set bit 4 to 1 to override the control of the USB_DM 15-KOhm pulldown. Clear to 0 to disable.
3–2 HSTPULLDOWN	Set bit 3 to 1 to pull down 15-KOhm on USB_DP line. Set bit 2 to 1 to pull down 15-KOhm on USB_DM line. Clear to 0 to disable.
1 DEBUG_INTERFACE_ HOLD	Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	Once OTG ID from USBPHY_STATUS_OTGID_STATUS is sampled, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

45.2.7 UTMI Debug Status Register 0 (USBPHY*x*_DEBUG0_STATUS)

The UTMI Debug Status Register 0 holds multiple views for counters and status of state machines. This is used in conjunction with the USBPHY_DEBUG1.DBG_ADDRESS field to choose which function to view. The default is described in the bit fields below and is used to count errors.

Address: Base address + 60h offset

Bit	31–26	25–16	15–0
R/W	SQUELCH_COUNT	UTMI_RXERROR_FAIL_COUNT	LOOP_BACK_FAIL_COUNT
Reset	0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

USBPHYx_DEBUG0_STATUS field descriptions

Field	Description
31–26 SQUELCH_ COUNT	Running count of the squelch reset instead of normal end for HS RX.
25–16 UTMI_ RXERROR_ FAIL_COUNT	Running count of the UTMI_RXERROR.
15–0 LOOP_BACK_ FAIL_COUNT	Running count of the failed pseudo-random generator loopback. Each time entering testmode, counter goes to 900D and will count up for every detected packet failure in digital/analog loopback tests.

45.2.8 UTMI Debug Status Register 1 (USBPHY*x*_DEBUG1*n*)

Chooses the muxing of the debug register to be shown in USBPHY_DEBUG0_STATUS.

Address: Base address + 70h offset + (4d × i), where i=0d to 3d

Bit	31–15	14–13	12–0
R	RSVD1	ENTAILADJVD	RSVD0
W			
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0	1 0 0 0 0 0 0 0 0 0 0 0 0

USBPHYx_DEBUG1n field descriptions

Field	Description
31–15 RSVD1	Reserved.
14–13 ENTAILADJVD	Delay increment of the rise of squelch: 00 = Delay is nominal 01 = Delay is +20% 10 = Delay is -20% 11 = Delay is -40%
12–0 RSVD0	Reserved. **Note:** This bit should remain clear.

45.2.9 UTMI RTL Version (USBPHYx_VERSION)

Fields for RTL Version.

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAJOR								MINOR								STEP															
W																																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

45.2.10 USB PHY IP Block Register (USBPHY*x*_IP*n*)

Address: Base address + 90h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	RSVD1													Reserved	Reserved	Reserved
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0													EN_USB_CLKS	PLL_LOCKED	PLL_POWER
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHY*x*_IP*n* field descriptions

Field	Description
31–19 RSVD1	Reserved.
18 Reserved	Setting this bit will not guarantee chip functionality. This field is reserved.
17 Reserved	Setting this bit will not guarantee chip functionality. This field is reserved.
16 Reserved	Setting this bit will not guarantee chip functionality. This field is reserved.
15–3 RSVD0	Reserved.

Table continues on the next page...

USBPHYx_IPn field descriptions (continued)

Field	Description
2 EN_USB_CLKS	If set to 0, 9-phase PLL outputs for USB PHY are powered down. If set to 1, 9-phase PLL outputs for USB PHY are powered up. Additionally, the UTMICLK120_GATE and UTMICLK30_GATE must be deasserted in the UTMI phy to enable USB operation. This bit came from the clkctrl PIO control block (clkctrl_pllctrl0_en_usb_clks).
1 PLL_LOCKED	Software controlled bit to indicate when the USB PLL has locked. Software needs to wait 10 us after enabling the PLL POWER bit (0) before asserting this bit. If set to 0, tells the UTMI module that the USB PLL has not locked. If set to 1, tells the UTMI module that the USB PLL has locked. Software should clear this bit prior to turning off the USB PLL. This bit came from the clkctrl module.
0 PLL_POWER	USB PLL Power On (0 = PLL off; 1 = PLL On). Allow 10 us after turning the PLL on before using the PLL as a clock source. This is the time the PLL takes to lock to 480 MHz. This bit came from the clkctrl PIO control block (clkctrl_pllctrl0_power).

45.3 USB Analog Memory Map/Register Definition

USB_ANALOG memory map

USB_ANALOG_USB0_VBUS_DETECT field descriptions

Field	Description
31 EN_CHARGER_RESISTOR	Enable 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB. This functionality is a legacy feature held over from USB Battery Charging Specification Revision 1.0 and is incompatible with either the plugged-in detector or Battery Charging Specification Revision 1.2. 0 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB is not enabled 1 Enable 125k pullup on USB_DP and 375k on USB_DM to provide USB_CHARGER functionality for USB
30–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 CHARGE_VBUS	USB OTG charge V_{BUS}. 0 Charging of the V_{BUS} is not enabled 1 Enable charging of the V_{BUS}
26 DISCHARGE_VBUS	USB OTG discharge V_{BUS}. 0 Discharging of the V_{BUS} is not enabled 1 Enable discharging of the V_{BUS}

Table continues on the next page...

USB_ANALOG_USB0_VBUS_DETECT field descriptions (continued)

Field	Description
25–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 VBUSVALID_ PWRUP_CMPS	Powers up comparators for $V_{BUS_}$valid detector. 0 Powering up comparators for $V_{BUS_}$valid detector is not enabled 1 Enable powering up comparators for $V_{BUS_}$valid detector.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 VBUSVALID_ TO_B	This bit muxes the Bvalid comparator to the VBUSVALID comparator and is used for test purposes only. 0 Multiplexing of the Bvalid comparator to the VBUSVALID comparator is not enabled 1 Enable multiplexing of the Bvalid comparator to the VBUSVALID comparator
17–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 VBUSVALID_ OVERRIDE	Override value for the VBUSVALID hardware signal. 0 Value for the VBUSVALID hardware signal is not overrided 1 Override value for the VBUSVALID hardware signal.
6 AVALID_ OVERRIDE	Override value for the AVALID hardware signal. 0 AVALID hardware signal is not overrided 1 Override value for the AVALID hardware signal
5 BVALID_ OVERRIDE	Override value for the BVALID hardware signal. 0 BVALID hardware signal is not overrided 1 Override value for the BVALID hardware signal
4 SESSEND_ OVERRIDE	Override value for the SESSEND hardware signal. 0 SESSEND hardware signal is not overrided 1 Override value for the SESSEND hardware signal
3 VBUS_ OVERRIDE_EN	Enable the override of the VBUSVALID, AVALID, BVALID, and SESSEND signals from the USB OTG PHY with override register bit values. 0 Use hardware generated values 1 Use the software controlled values.
2–0 VBUSVALID_ THRESH	Set the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50mV of hysteresis to prevent chattering at the comparator trip point. 000 4.0 V 001 4.1 V 010 4.2 V 011 4.3 V 100 4.4 V (default) 101 4.5 V 110 4.6 V 111 4.7 V

45.3.2 USB0 Charger Detect control register (USB_ANALOG_USB0_CHRG_DETECT)

This register defines the control bits for the USB charger detector of USB0.

Address: 4005_0000h base + 1B0h offset = 4005_01B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USB_ANALOG_USB0_CHRG_DETECT field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 CHRG_DET_ CTRL	Forces internal USB charging circuitery to enable basic USB battery charging v1.1 device charger detection functionality. 0 USB battery charging v1.1 device charger detection functionality is not enabled 1 Enable basic USB battery charging v1.1 device charger detection functionality
21 CHRG_DET_ STATUS	Status of internal charge detection. 0 Charger not detected. 1 Charger detected.
20 EN_B	This bit enables the charger detector. 0 Enable the charger detector. 1 Disable the charger detector.
19 CHK_CHRG_B	This bit checks whether a charger (either a dedicated charger or a host charger) is connected to USB port. 0 Check whether a charger (either a dedicated charger or a host charger) is connected to USB port. 1 Do not check whether a charger is connected to the USB port.
18 CHK_CONTACT	This bit checks whether the USB plug has been in contact with each other. 0 Do not check the contact of USB plug. 1 Check whether the USB plug has been in contact with each other.
17–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 FORCE_ DETECT	Set this bit to 1 to force the charger detector circuit to signal the presence of a charger. 0 The charger detector circuit is not forced to signal the presence of a charger. 1 Force the charger detector circuit to signal the presence of a charger.

45.3.3 USB0 V_{BUS} Detect Status definition register (USB_ANALOG_USB0_VBUS_DETECT_STATUS)

This register defines the status bits of the V_{BUS} detectors of USB1.

Address: 4005_0000h base + 1C0h offset = 4005_01C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USB_ANALOG_USB0_VBUS_DETECT_STATUS field descriptions

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

USB_ANALOG_USB0_VBUS_DETECT_STATUS field descriptions (continued)

Field	Description
3 VBUS_VALID	V_{BUS} valid for USB OTG. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software. 0 V_{BUS} not valid for USB OTG 1 V_{BUS} valid for USB OTG
2 AVALID	Indicates V_{BUS} is valid for a A-peripheral. This bit is a read only version of the state of the analog signal. It cannot be overritten by software. 0 V_{BUS} is not valid for a A-peripheral 1 V_{BUS} is valid for a A-peripheral
1 BVALID	V_{BUS} valid for USB B-session. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software. 0 V_{BUS} is not valid for USB B-session 1 V_{BUS} valid for USB B-session
0 SESSEND	Session end for USB OTG. This bit is a read only version of the state of the analog signal. It cannot be overwritten by software like the SESSEND bit below. Note: This bit's default value depends on whether VDD5V is present. 0 VDD5V is present. 1 VDD5V is not present.

45.3.4 USB0 Charger Detect Status definition register (USB_ANALOG_USB0_CHRG_DETECT_STATUS)

This register defines the status bits for the USB charger detector of USB1.

Address: 4005_0000h base + 1D0h offset = 4005_01D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USB_ANALOG_USB1_MISC field descriptions (continued)

Field	Description
0 HS_USE_ EXTERNAL_R	Use external resistor to generate the current bias for the high speed transmitter. This bit should not be changed unless recommended by Freescale.

45.4 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in Figure 45-116.

45.4.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL supplies a 120 MHz signal to all of the digital logic. The UTMI block does a final divide-by-four to develop the 30 MHz clock used in the interface.

45.4.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

45.4.3 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and a 9X, 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

45.4.4 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module

, as shown in the figure below and described further in this section.

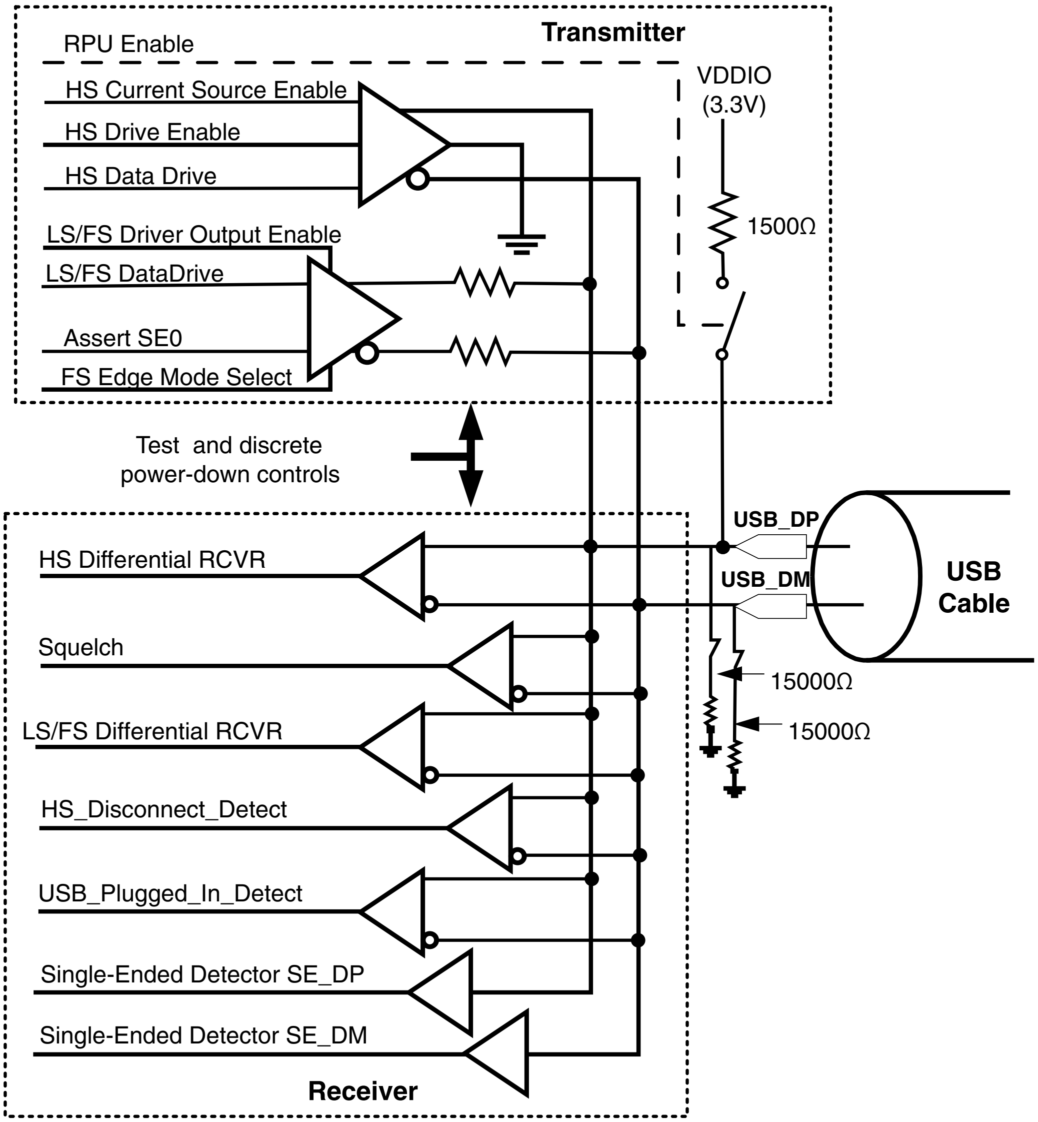

Figure 45-116. USB 2.0 PHY Analog Transceiver Block Diagram

45.4.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.

Otherwise, its output is 0. Its purpose is to discriminate the ± 400-mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each leg of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

45.4.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

45.4.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB_DP line is above the crossover point and the USB_DM line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

45.4.4.4 HS Disconnect Detector

This host-side function is not used in applications, but is included to make a complete UTMI macrocell. It is a differential analog receiver and threshold comparator.

It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

45.4.4.5 USB Plugged-In Detector

The USB plugged-in detector looks for both USB_DP and USB_DM to be high. There is a pair of large on-chip pullup resistors (200 KΩ) that hold both USB_DP and USB_DM high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case.

When operating in device mode, the upstream port in host/hub interface contains a 15 KΩ pulldown resistor which could easily override the 200 KΩ pullup resistor. When plugged in, at least one signal in the pair will be low, which will force the plugged-in detector's output high.

45.4.4.6 Single-Ended USB_DP Receiver

The single-ended USB_DP receiver output is high whenever the USB_DP input is above its nominal 1.8 V threshold.

45.4.4.7 Single-Ended USB_DM Receiver

The single-ended USB_DM receiver output is high whenever the USB_DM input is above its nominal 1.8 V threshold.

45.4.4.8 9X Oversample Module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

45.4.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 KΩ pullup resistor.

See Figure 1.

45.4.5.1 Switchable High-Speed 45Ω Termination Resistors

High-speed current mode differential signaling requires good 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are

provided to tune the actual termination resistance of each device, as shown in Figure 1. The USBPHY_TX_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45Ω terminator on the USB_DP signal.

45.4.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially "open drain" low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

The tx_ls_en signal is used to select the USB_DP/USB_DM edge for low-speed or full-speed. Setting this bit to 1 selects the low-speed driver; otherwise the full-speed driver is selected. These drivers are both turned on, simultaneously, for high-speed signaling. This has the effect of switching in both 45 Ω terminating resistors. The tx_fs_hiz signal originates in the digital transmitter section. The hs_term signal that also controls these drivers comes from the UTMI.

45.4.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB_DP signal or the USB_DM signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit. The Iref, Ibias, and V to I circuits are shared with the integrated battery charger.

45.4.5.4 Switchable 1.5KΩ USB_DP Pullup Resistor

This product contains a switchable 1.5 KΩ pullup resistor on the USB DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

45.4.5.5 Switchable 15KΩ USB_DP Pulldown Resistor

This product contains a switchable 15 KΩ pulldown resistor on both USB_DP and USB_DM signals. This is used in host mode to indicate to the device controller that a host is present.

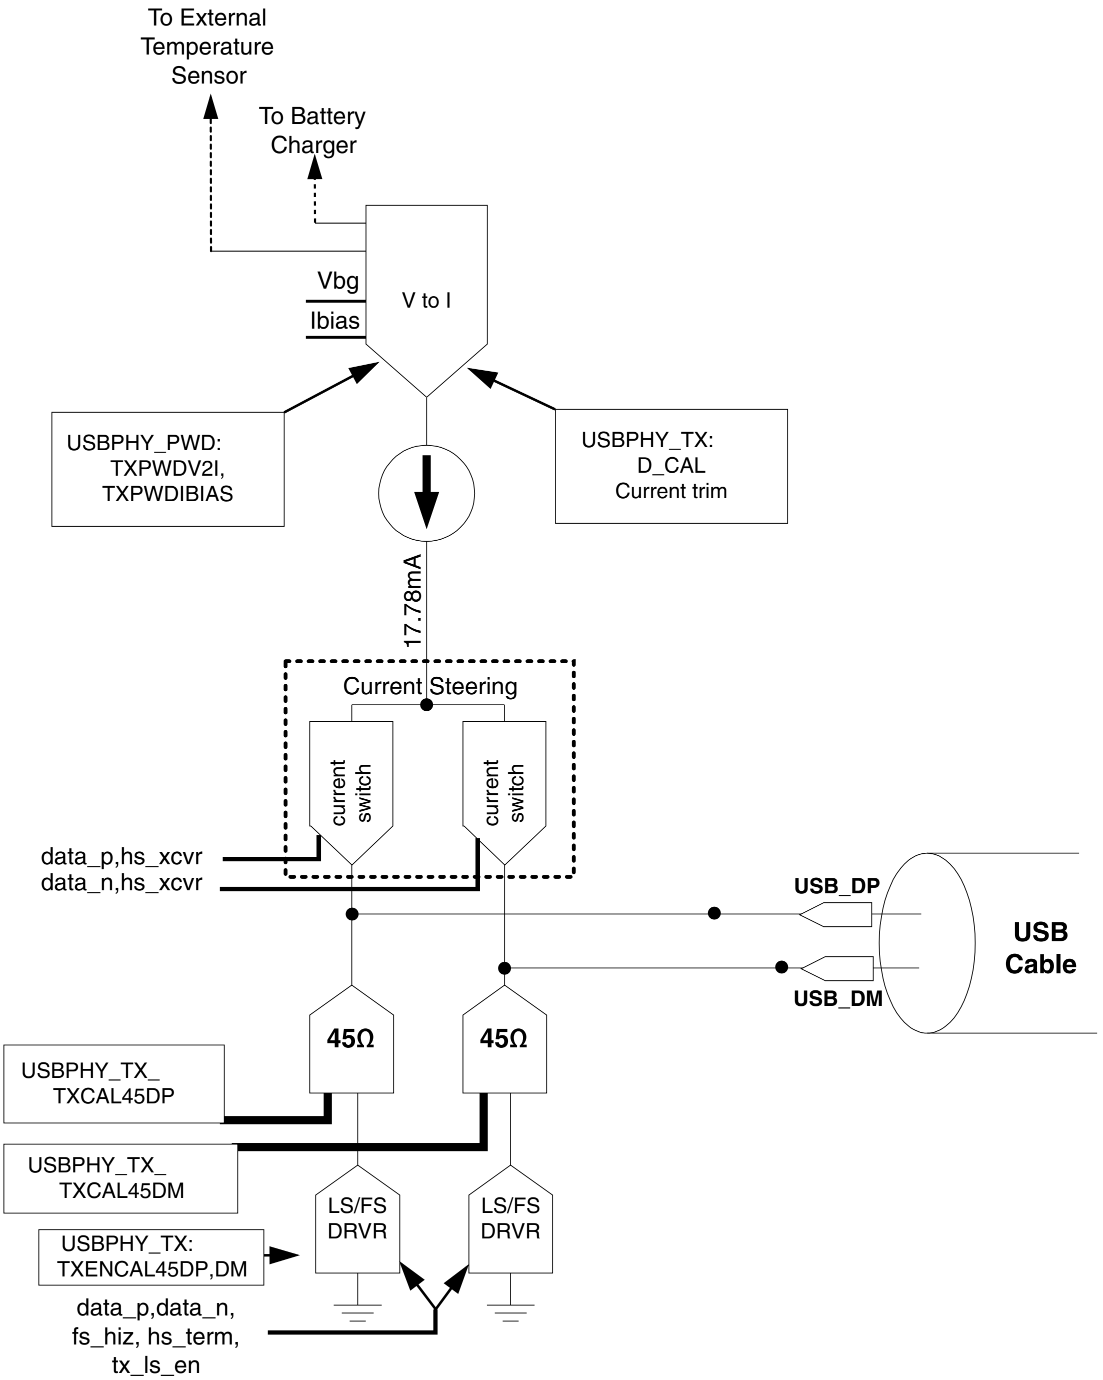

Figure 45-117. USB 2.0 PHY Transmitter Block Diagram

The table below summarizes the response of the PHY analog transmitter to various states of UTMI input and key transmit/receive state machine states.

Table 45-119. USB PHY Terminator States

45.4.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

HW_USBPHY_TX_TXCAL45DP = 0x0
HW_USBPHY_TX_TXCAL45DM = 0x0
HW_USBPHY_TX_D_CAL = 0x7

Chapter 46
CAN (FlexCAN)

46.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0 B protocol specification. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive (Rx) Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

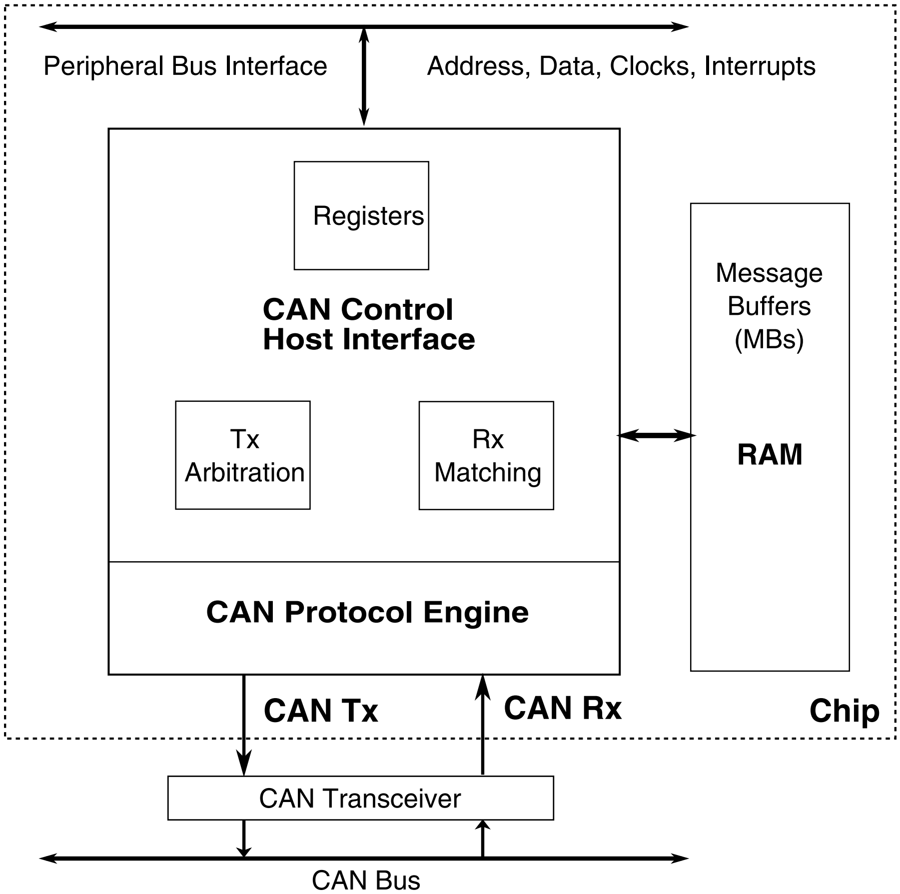

Figure 46-1. FlexCAN block diagram

46.1.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the MCU.

The CAN Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames

- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

46.1.2 FlexCAN module features

The FlexCAN module includes these distinctive legacy features:

- Full implementation of the CAN protocol specification, Version 2.0 B
    - Standard data and remote frames
    - Extended data and remote frames
    - Zero to eight bytes data length
    - Programmable bit rate up to 1 Mb/sec
    - Content-related addressing
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused structures space can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation

- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes

New major features are also provided:

- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors).

46.1.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at MCU level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Listen-Only mode:

  The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back mode:

  The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See Module Disable mode for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at MCU level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See Stop mode for more information.

46.2 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external MCU pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 46-1. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

46.2.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

46.2.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

46.3 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the MCU.

46.3.1 FlexCAN memory mapping

The complete memory map for a FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of Table 46-2.

Table 46-2. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 register (CTRL1)	S/U	Yes	No
Free Running Timer register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control Register (MECR)	S/U	Yes	Yes
Error Injection Address Register (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern Register (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern Register (ERRIPPR)	S/U	Yes	Yes
Error Report Address Register (RERRAR)	S/U	Yes	Yes
Error Report Data Register (RERRDR)	S/U	Yes	Yes
Error Report Syndrome Register (RERRSYNR)	S/U	Yes	Yes
Error Status Register (ERRSR)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

This module's memory map includes sixty-four 128-bit message buffers (MBs) that occupy the range from offset 0x80 to 0x47F.

CAN memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4002_0000	Module Configuration Register (CAN0_MCR)	32	R/W	5980_000Fh	46.3.2/2438

CANx_MCR field descriptions

Field	Description
31 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This is the only bit within this register not affected by soft reset. 0 Enable the FlexCAN module. 1 Disable the FlexCAN module.
30 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR Register is set or when Debug mode is requested at MCU level . When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. 0 Not enabled to enter Freeze mode. 1 Enabled to enter Freeze mode.
29 RFEN	Rx FIFO Enable This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in section "Arbitration and Matching Timing"). This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Rx FIFO not enabled. 1 Rx FIFO enabled.
28 HALT	Halt FlexCAN

Table continues on the next page...

CANx_MCR field descriptions (continued)

Field	Description
	Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode. 0 No Freeze mode request. 1 Enters Freeze mode if the FRZ bit is asserted.
27 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode , Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes. 0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode. 1 FlexCAN module is either in Disable mode , Stop mode or Freeze mode.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 SOFTRST	Soft Reset When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER , ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, all RXIMR registers, RXMGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR, all Message Buffers . The SOFTRST bit can be asserted directly by the CPU when it writes to the MCR Register, but it is also asserted when global soft reset is requested at MCU level. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. 0 No reset request. 1 Resets the registers affected by soft reset.
24 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode". **NOTE:** FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing"). 0 FlexCAN not in Freeze mode, prescaler running. 1 FlexCAN in Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only . This bit can be written only in Freeze mode because it is blocked by hardware in other modes.

Table continues on the next page...

CANx_MCR field descriptions (continued)

Field	Description
	0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses . 1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location .
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
20 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode , Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. **NOTE:** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing"). 0 FlexCAN is not in a low-power mode. 1 FlexCAN is in a low-power mode.
19 Reserved	This field is reserved.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Self reception enabled. 1 Self reception disabled.
16 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 Individual Rx masking and queue feature are enabled.
15 Reserved	This field is reserved.

Table continues on the next page...

CANx_MCR field descriptions (continued)

Field	Description
14 Reserved	This field is reserved.
13 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Local Priority disabled. 1 Local Priority enabled.
12 AEN	Abort Enable This bit is supplied for backwards compatibility with legacy applications. When asserted, it enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** When MCR[AEN] is asserted, only the abort mechanism (see Section "Transmission Abort Mechanism") must be used for updating Mailboxes configured for transmission. **CAUTION:** Writing the Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted. 0 Abort disabled. 1 Abort enabled.
11–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00 Format A: One full ID (standard and extended) per ID Filter Table element. 01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element. 10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element. 11 Format D: All frames rejected.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–0 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE:** MAXMB must be programmed with a value smaller than the parameter NUMBER_OF_MB, otherwise the number of the last effective Message Buffer will be: (NUMBER_OF_MB - 1)

Table continues on the next page...

CANx_MCR field descriptions (continued)

Field	Description
	Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in Section "Arbitration and Matching Timing").

46.3.3 Control 1 register (CANx_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: Base address + 4h offset

CANx_CTRL1 field descriptions

Field	Description
31–24 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1)
23–22 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.

Table continues on the next page...

CANx_CTRL1 field descriptions (continued)

Field	Description
21–19 PSEG1	Phase Segment 1 This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
18–16 PSEG2	Phase Segment 2 This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
15 BOFFMSK	Bus Off Mask This bit provides a mask for the Bus Off Interrupt. 0 Bus Off interrupt disabled. 1 Bus Off interrupt enabled.
14 ERRMSK	Error Mask This bit provides a mask for the Error Interrupt. 0 Error interrupt disabled. 1 Error interrupt enabled.
13 CLKSRC	CAN Engine Clock Source This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock (driven by the PLL) or the crystal oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclock). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Section "Protocol Timing". 0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock. 1 The CAN engine clock source is the peripheral clock.
12 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** In this mode, the MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message. 0 Loop Back disabled. 1 Loop Back enabled.
11 TWRNMSK	Tx Warning Interrupt Mask

Table continues on the next page...

CANx_CTRL1 field descriptions (continued)

Field	Description
	This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0 Tx Warning Interrupt disabled. 1 Tx Warning Interrupt enabled.
10 RWRNMSK	Rx Warning Interrupt Mask This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0 Rx Warning Interrupt disabled. 1 Rx Warning Interrupt enabled.
9–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Just one sample is used to determine the bit value. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.
6 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B. 1 Automatic recovering from Bus Off state disabled.
5 TSYN	Timer Sync This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in MCR is set (Rx FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Timer Sync feature disabled 1 Timer Sync feature enabled
4 LBUF	Lowest Buffer Transmitted First

Table continues on the next page...

CANx_CTRL1 field descriptions (continued)

Field	Description
	This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIOEN bit does not affect the priority arbitration. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Buffer with highest priority is transmitted first. 1 Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the REC, as if it was trying to acknowledge the message. Listen-Only mode acknowledgement can be obtained by the state of ESR1[FLTCONF] field which is Passive Error when Listen-Only mode is entered. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Listen-Only mode is deactivated. 1 FlexCAN module operates in Listen-Only mode.
2–0 PROPSEG	Propagation Segment This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.

46.3.4 Free Running Timer (CANx_TIMER)

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable , Stop, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure; see Section "Mailbox Lock Mechanism".

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–0 TIMER	Timer Value Contains the free-running counter value.

46.3.5 Rx Mailboxes Global Mask Register (CANx_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the MCR[IRMQ] bit is negated, RXMGMASK is always in effect.
- When the MCR[IRMQ] bit is asserted, RXMGMASK has no effect.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

CANx_RXMGMASK field descriptions

Field	Description
31–0 MG[31:0]	Rx Mailboxes Global Mask Bits

CANx_RXMGMASK field descriptions (continued)

Field	Description
	These bits mask the Mailbox filter bits. Note that the alignment with the ID word of the Mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the Mailbox. The following table shows in detail which MG bits mask each Mailbox filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	note [2]	note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

46.3.6 Rx 14 Mask register (CANx_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CANx_RX15MASK field descriptions

Field	Description
31–0 RX15M[31:0]	Rx Buffer 15 Mask Bits Each mask bit masks the corresponding Mailbox 15 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register. 0 The corresponding bit in the filter is "don’t care." 1 The corresponding bit in the filter is checked.

46.3.8 Error Counter (CANx_ECR)

This register has two 8-bit fields reflecting the value of two FlexCAN error counters: Transmit Error Counter (TXERRCNT field) and Receive Error Counter (RXERRCNT field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read-only except in Freeze mode, where they can be written by the CPU.

FlexCAN responds to any bus state as described in the protocol, for example, transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in Bus Off state.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect ‘Error Passive’ state.
- If the FlexCAN state is ‘Error Passive’, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect ‘Error Active’ state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect ‘Bus Off’ state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in ‘Bus Off’ state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be ‘Error Active’ and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to ‘Error Passive’ state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the ‘Bus Off’ state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to ‘Error Active’ state.

Address: Base address + 1Ch offset

Bit	31–16	15–8	7–0
R	0	RXERRCNT	TXERRCNT
W

CANx_ECR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–8 RXERRCNT	Receive Error Counter
7–0 TXERRCNT	Transmit Error Counter

46.3.9 Error and Status 1 register (CANx_ESR1)

This register reflects various error conditions, some general status of the device and it is the source of interrupts to the CPU.

The CPU read action clears bits 15-10. Therefore the reported error conditions (bits 15-10) are those that occurred since the last time the CPU read this register. Bits 9-3 are status bits.

The following table shows the FlexCAN state variables and their meanings. Other combinations not shown in the table are reserved.

SYNCH	IDLE	TX	RX	FlexCAN State
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

Address: Base address + 20h offset

CANx_ESR1 field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not synchronized to the CAN bus. 1 FlexCAN is synchronized to the CAN bus.
17 TWRNINT	Tx Warning Interrupt Flag If the WRNEN bit in MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Tx error counter transitioned from less than 96 to greater than or equal to 96.
16 RWRNINT	Rx Warning Interrupt Flag If the WRNEN bit in MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.

Table continues on the next page...

CANx_ESR1 field descriptions (continued)

Field	Description
	NOTE: This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. 0 No such occurrence. 1 An ACK error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error This bit indicates that a CRC Error has been detected by the receiver node, that is, the calculated CRC is different from the received. 0 No such occurrence. 1 A CRC error occurred since last read of this register.
11 FRMERR	Form Error This bit indicates that a Form Error has been detected by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. 0 No such occurrence. 1 A Form Error occurred since last read of this register.
10 STFERR	Stuffing Error This bit indicates that a Stuffing Error has been etected. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.
9 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission. This bit is not updated during Freeze mode. 0 No such occurrence. 1 TXERRCNT is greater than or equal to 96.
8 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception. This bit is not updated during Freeze mode. 0 No such occurrence. 1 RXERRCNT is greater than or equal to 96.

Table continues on the next page...

CANx_ESR1 field descriptions (continued)

Field	Description
7 IDLE	This bit indicates when CAN bus is in IDLE state. See the table in the overall CAN_ESR1 register description. 0 No such occurrence. 1 CAN bus is now IDLE.
6 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not transmitting a message. 1 FlexCAN is transmitting a message.
5–4 FLTCONF	Fault Confinement State This 2-bit field indicates the Confinement State of the FlexCAN module. If the LOM bit in the Control Register is asserted, after some delay that depends on the CAN bit timing the FLTCONF field will indicate “Error Passive”. The very same delay affects the way how FLTCONF reflects an update to ECR register by the CPU. It may be necessary up to one CAN bit time to get them coherent again. Because the Control Register is not affected by soft reset, the FLTCONF field will not be affected by soft reset if the LOM bit is asserted. 00 Error Active 01 Error Passive 1x Bus Off
3 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not receiving a message. 1 FlexCAN is receiving a message.
2 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters ‘Bus Off’ state. If the corresponding mask bit in the Control Register (BOFFMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit in the Error and Status Register.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.3.10 Interrupt Masks 2 register (CANx_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

Address: Base address + 24h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BUFHM																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CANx_IMASK2 field descriptions

Field	Description
31–0 BUFHM	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB63 to MB32. **NOTE:** Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

46.3.11 Interrupt Masks 1 register (CANx_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BUFLM

CANx_IMASK1 field descriptions

Field	Description
31–0 BUFLM	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0. **NOTE:** Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

46.3.12 Interrupt Flags 2 register (CANx_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG2 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: Base address + 2Ch offset

Bit	31–0
R	BUFHI
W	w1c
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

CANx_IFLAG2 field descriptions

Field	Description
31–0 BUFHI	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB63 to MB32. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.

46.3.13 Interrupt Flags 1 register (CANx_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit MCR[RFEN] is set, the function of the 8 least significant interrupt flags BUF[7:0]I changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, and the BUF4TO0I field is reserved.

Before enabling the RFEN, the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when an RFFN value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

Before updating MCR[MAXMB] field, CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: Base address + 30h offset

CANx_IFLAG1 field descriptions

Field	Description
31–8 BUF31TO8I	Buffer MB_i Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt Or "Rx FIFO Overflow" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE:** This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF7I flag represents "Rx FIFO Overflow" when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. 0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
6 BUF6I	Buffer MB6 Interrupt Or "Rx FIFO Warning" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE:** This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF6I flag represents "Rx FIFO Warning" when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4. 0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
5 BUF5I	Buffer MB5 Interrupt Or "Frames available in Rx FIFO" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5. **NOTE:** This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF5I flag represents "Frames available in Rx FIFO" when MCR[RFEN] is set. In this case, the flag indicates that at least one frame is available to be read from the Rx FIFO. 0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1
4–1 BUF4TO1I	Buffer MB_i Interrupt Or "reserved" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE:** These flags are cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when MCR[RFEN] is set.

Table continues on the next page...

CANx_IFLAG1 field descriptions (continued)

Field	Description
	0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
0 BUF0I	Buffer MB0 Interrupt Or "reserved" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0. **NOTE:** This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF0I flag is reserved when MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

46.3.14 Control 2 register (CANx_CTRL2)

This register contains control bits for CAN errors, FIFO features, and mode selection.

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CANx_CTRL2 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 ECRWRE	Error-correction Configuration Register Write Enable Enable that the MECR register is updated. This bit is automatically set to 0 if the protocol described in the "Detection and Correction of Memory Errors" section is not followed. 0 Disable update. 1 Enable update.
28 WRMFRZ	Write-Access To Memory In Freeze Mode

Table continues on the next page...

CANx_CTRL2 field descriptions (continued)

Field	Description
	Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. 0 Maintain the write access restrictions. 1 Enable unrestricted write access to FlexCAN memory.
27–24 RFFN	Number Of Rx FIFO Filters This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the MCU. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by MCR[MAXMB]. **NOTE:** Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value correponding to a number of filters not greater than the number of available memory words which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the least between NUMBER_OF_MB and MAXMB. The number of remaining Mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional.

RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes[1]	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks[2]	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask [2]

Table continues on the next page...

CANx_CTRL2 field descriptions (continued)

Field	Description
	(continued from previous page)

RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes[1]	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks[2]	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask [2]
0xF	128	MB 0-37	MB 38-63	Elements 0-31	Elements 32-127

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER_OF_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

23–19 TASD

Tx Arbitration Start Delay

This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can be written only in Freeze mode because it is blocked by hardware in other modes.

This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa.

If TASD is 0 then the arbitration start is not delayed, thus the CPU has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. On the other hand, if TASD is 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration.

If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is not the best to be transmitted.

The optimal configuration for TASD can be calculated as:

$$TASD = 25 - \{f_{CANCLK} \times [MAXMB + 3 - (RFEN \times 8) - (RFEN \times RFFN \times 2)] \times 2\} / \{f_{SYS} \times [1+(PSEG1+1)+(PSEG2+1)+(PROPSEG+1)] \times (PRESDIV+1)\}$$

where:

- f_{CANCLK} is the Protocol Engine (PE) Clock (see section "Protocol Timing"), in Hz
- f_{SYS} is the peripheral clock, in Hz
- MAXMB is the value in CTRL1[MAXMB] field
- RFEN is the value in CTRL1[RFEN] bit
- RFFN is the value in CTRL2[RFFN] field
- PSEG1 is the value in CTRL1[PSEG1] field
- PSEG2 is the value in CTRL1[PSEG2] field
- PROPSEG is the value in CTRL1[PROPSEG] field
- PRESDIV is the value in CTRL1[PRESDIV] field

See Section "Arbitration process" and Section "Protocol Timing" for more details.

Table continues on the next page...

CANx_CTRL2 field descriptions (continued)

Field	Description
18 MRP	Mailboxes Reception Priority If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Matching starts from Rx FIFO and continues on Mailboxes. 1 Matching starts from Mailboxes and continues on Rx FIFO.
17 RRS	Remote Request Storing If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated. If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Remote Response Frame is generated. 1 Remote Request Frame is stored.
16 EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes This bit controls the comparison of IDE and RTR bits whithin Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER_OF_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

46.3.15 Error and Status 2 register (CANx_ESR2)

This register reflects various interrupt flags and some general status.

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0									LPTM						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	VPS	IMB	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CANx_ESR2 field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 VPS	Valid Priority Status This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. **NOTE:** ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0 Contents of IMB and LPTM are invalid. 1 Contents of IMB and LPTM are valid.
13 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases: • During arbitration, if an LPTM is found and it is inactive. • If IMB is not asserted and a frame is transmitted successfully. This bit is cleared in all start of arbitration (see Section "Arbitration process"). **NOTE:** LPTM mechanism have the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive Mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox. 1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.
12–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.3.16 CRC Register (CANx_CRCR)

This register provides information about the CRC of transmitted messages.

Address: Base address + 44h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0									MBCRC						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	TXCRC														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CANx_CRCR field descriptions

Field	Description
31–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 MBCRC	CRC Mailbox This field indicates the number of the Mailbox corresponding to the value in TXCRC field.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–0 TXCRC	CRC Transmitted This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted.

46.3.17 Rx FIFO Global Mask register (CANx_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 48h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CANx_RXFGMASK field descriptions

Field	Description
31–0 FGM[31:0]	Rx FIFO Global Mask Bits These bits mask the ID Filter Table elements bits in a perfect alignment. The following table shows how the FGM bits correspond to each IDAF field.

Rx FIFO ID Filter Table Elements Format (MCR[IDAM])	Identifier Acceptance Filter Fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	-	-	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	-	FGM[29:16], FGM[13:0]		-
C	-	-		-	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

46.3.18 Rx FIFO Information Register (CANx_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:

- x = Undefined at reset.

CANx_RXFIR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–0 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted.

46.3.19 Rx Individual Mask Registers (CANx_RXIMR*n*)

These registers are located in RAM.

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on the setting of CTRL2[RFFN].

RXIMR can only be written by the CPU while the module is in Freeze mode; otherwise, they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: Base address + 880h offset + (4d × i), where i=0d to 63d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CANx_MECR field descriptions

Field	Description
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. 0 Write is enabled. 1 Write is disabled.
30–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 HANCEI_MSK	Host Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the host (CPU).

Table continues on the next page...

CANx_MECR field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
18 FANCEI_MSK	FlexCAN Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the FlexCAN internal processes. 0 Interrupt is disabled. 1 Interrupt is enabled.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt in case of correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 Injection is disabled. 1 Injection is enabled.
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0 Injection is disabled. 1 Injection is enabled.
13 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern Register (FCERRIDPR) and Error Injection Parity Pattern Register (FCERRIPPR) 0 Error injection is applied only to the 32-bit word. 1 Error injection is applied to the 64-bit word.
12–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE:** When reading the report registers, this bit must be cleared to assure coherence on the consecutive register reads. 0 Enable updates of the error report registers. 1 Disable updates of the error report registers.
8 ECCDIS	Error Correction Disable

Table continues on the next page...

CANx_MECR field descriptions (continued)

Field	Description
	Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0 Enable memory error correction. 1 Disable memory error correction.
7 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. The option to enter Freeze mode is a safety measure to prevent corrupted data from being treated as valid by FlexCAN internal processes. 0 Keep normal operation. 1 Put FlexCAN in Freeze mode (according to the "Freeze mode" section).
6–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.3.21 Error Injection Address Register (CANx_ERRIAR)

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM:

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	-
MBs	0x0000	0x0080
Reserved	-	0x0480
RXIMRs	0x0400	0x0880
Reserved	-	0x0980
RXFIR_0	0x0500	0x0A80
RXFIR_1	0x0504	0x0A84

4–0 PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

46.3.24 Error Report Address Register (CANx_RERRAR)

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word in which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Address: Base address + AF0h offset

CANx_RERRDR field descriptions

Field	Description
31–0 RDATA	Raw data word read from memory with error

46.3.26 Error Report Syndrome Register (CANx_RERRSYNR)

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 46-187. Syndrome Definition

SYNDn (hex)	Type	Bit affected
00	-	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6

Table continues on the next page...

Table 46-187. Syndrome Definition (continued)

SYNDn (hex)	Type	Bit affected
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
All others	-	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

CANx_ERRSR field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 HANCEIF	Host Access With Non-Correctable Error Interrupt Flag Indicates that a non-correctable error was detected in a memory access initiated by Host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] is set, the interrupt is asserted. 0 No non-correctable errors were detected in Host accesses so far. 1 A non-correctable error was detected in a Host access.
18 FANCEIF	FlexCAN Access With Non-Correctable Error Interrupt Flag

Table continues on the next page...

CANx_ERRSR field descriptions (continued)

Field	Description
	Indicates that a non-correctable error was detected in a memory access initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] is set, the interrupt is asserted. 0 No non-correctable errors were detected in FlexCAN accesses so far. 1 A non-correctable error was detected in a FlexCAN access.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory access. If MECR[CEI_MSK] is set, the interrupt is asserted. 0 No correctable errors were detected so far. 1 A correctable error was detected.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory access initiated by Host when HANCEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.) 0 No overrun on non-correctable errors in Host access 1 Overrun on non-correctable errors in Host access
2 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory access initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.) 0 No overrun on non-correctable errors in FlexCAN access 1 Overrun on non-correctable errors in FlexCAN access
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory access when CEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.) 0 No overrun on correctable errors 1 Overrun on correctable errors

46.3.80 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x47C is used by the mailboxes.

Table 46-282. Message buffer structure

	31 30 29 28	27 24	23	22	21	20	19 18 17 16	15 8	7 0
0x0		CODE		SRR	IDE	RTR	DLC	TIME STAMP	
0x4	PRIO	ID (Standard/Extended)						ID (Extended)	
0x8	Data Byte 0		Data Byte 1					Data Byte 2	Data Byte 3
0xC	Data Byte 4		Data Byte 5					Data Byte 6	Data Byte 7

(shaded) = Unimplemented or Reserved

CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 46-283 and Table 46-284. See Functional description for additional information.

Table 46-283. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0000: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0b0100: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the Move-in) process), the CODE field is automatically updated to FULL.

Table continues on the next page...

Table 46-283. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0010: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0b0110: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 46-283. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b1010: RANSWER[4] — A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.	RANSWER	—	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See Matching process for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1b1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[5]	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit from CTRL2 register. See section "Control 2 Register (CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 46-284. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.

Table continues on the next page...

Table 46-284. Message buffer code for Tx buffers (continued)

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1001: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
0b1100: DATA — MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE — MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER — MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 46-283, Table 46-284, and the description of the RRS bit in Control 2 Register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see the Table 46-282). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 46-285).

TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO — Local priority

This 3-bit field is used only when LPRIO_EN bit is set in MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0–7 — Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

Table 46-285. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0–1
3	DATA BYTE 0–2
4	DATA BYTE 0–3
5	DATA BYTE 0–4
6	DATA BYTE 0–5
7	DATA BYTE 0–6
8	DATA BYTE 0–7

46.3.81 Rx FIFO structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

Table 46-286. Rx FIFO structure

	31	28	24	23	22	21	20	19	18	17	16	15	8	7	0
0x80	(reserved)				SRR	IDE	RTR	DLC				TIME STAMP			
0x84	(reserved)	ID standard								ID extended					
0x88	Data byte 0			Data byte 1								Data byte 2		Data byte 3	
0x8C	Data byte 4			Data byte 5								Data byte 6		Data byte 7	
0x90 to 0xDC	Reserved														
0xE0	ID filter table element 0														
0xE4	ID filter table element 1														
0xE8 to 0x2D4	ID filter table elements 2 to 125														
0x2D8	ID filter table element 126														
0x2DC	ID filter table element 127														
	(reserved) = Unimplemented or reserved														

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Table 46-287. ID table structure

Format	31	30	29	24	23	16	15	14	13	8	7	1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)										(reserved)
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)				RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)				
C	RXIDC_0 (std/ext = 31–24)				RXIDC_1 (std/ext = 23–16)		RXIDC_2 (std/ext = 15–8)				RXIDC_3 (std/ext = 7–0)		
	(reserved) = Unimplemented or Reserved												

RTR — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

IDE — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

46.4 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range

of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to Table 46-283). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to Table 46-284).

46.4.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism). If backwards compatibility is desired (MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see Mailbox inactivation).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see Table 46-283 and Table 46-284 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

46.4.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIOEN] bits settings.

46.4.2.1 Lowest-number Mailbox first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIOEN] bit has no effect when CTRL1[LBUF] is asserted.

46.4.2.2 Highest-priority Mailbox first

If CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN] bit setting.

46.4.2.2.1 Local Priority disabled

If MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

Table 46-288. Composition of the arbitration value when Local Priority is disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

46.4.2.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 46-289. Composition of the arbitration value when Local Priority is enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

46.4.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the Data Length Code (DLC) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. TASD value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX_ERR_CNT=124 to 128. TASD value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.

  - If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

46.4.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see Move-in) as follows:

1. The received Data field (8 bytes at most) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 46-283 and Table 46-284 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU

services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 46-283 . If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

CAUTION

In summary: *never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRXDIS] bit is not asserted. If the MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the IFLAG[BUF5I] "Frames available in Rx FIFO" bit in the IMASK1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional – needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional – needed only if a mask was used)
3. Read the Data field
4. Read the RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory – releases the MB and allows the CPU to read the next Rx FIFO entry)

46.4.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is

found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 46-290. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	-	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN

Table continues on the next page...

Table 46-290. Matching architecture (continued)

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO[5]	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no_cmp: The SMB contents are not compared with the MB contents
4. cmp_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism)
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
    - If MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox
    - If MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

Table 46-291. Matching possibilities and resulting reception structures

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	-[3]	None	Frame lost by no match
0	0	X	Free[4]	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull[6]	FIFO	
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)

Table continues on the next page...

Table 46-291. Matching possibilities and resulting reception structures (continued)

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMb	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see Mailbox inactivation) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Refer to the description of the Rx Individual Mask Registers (RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RGXMASK, RX14MASK, RX15MASK and RXFGMASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

46.4.5 Move process

There are two types of move process: move-in and move-out.

46.4.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process

- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see Mailbox inactivation) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

46.4.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

46.4.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

46.4.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode

- The module enters in BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.
- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

46.4.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instruction on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can lead to undesirable results:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without notice

In order to eliminate such risk and perform a *safe inactivation* the CPU must use the following mechanism along with the inactivation itself:

- For Tx Mailboxes, the Transmission Abort (see Transmission abort mechanism)

The inactivation automatically unlocks the Mailbox (see Mailbox lock mechanism).

NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

46.4.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking is done to prevent a new frame to be written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of FIFO and have a code different than INACTIVE

(0b0000) or EMPTY[1] (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation) and it will take place only when the module resumes to Normal or Freeze modes.

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

46.4.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the IRMQ bit is negated, then the FIFO filter table is affected by RXFGMASK.

46.4.8 CAN protocol related features

This section describes the CAN protocol related features.

46.4.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer

immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

46.4.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

46.4.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in the description of the Control 1 Register (CTRL1).

46.4.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock (generally from a PLL). In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (bit MDIS set in the Module Configuration Register).

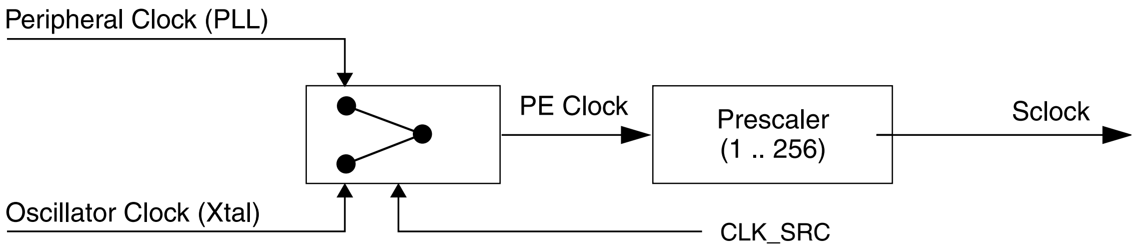

Figure 46-272. CAN engine clocking scheme

The crystal oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than PLL generated clocks.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See the description of the Control 1 Register (CTRL1).

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler Value})}$$

A bit time is subdivided into three segments[2] (see Figure 46-273 and Table 46-292):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section

2. For further explanation of the underlying concepts, see ISO/DIS 11519–1, Section 10.3. See also the CAN 2.0A/B protocol specification for bit timing.

- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL1 Register (plus 1) to be 2 to 8 time quanta long

$$\text{Bit Rate} = \frac{f_{Tq}}{\text{(number of Time Quanta)}}$$

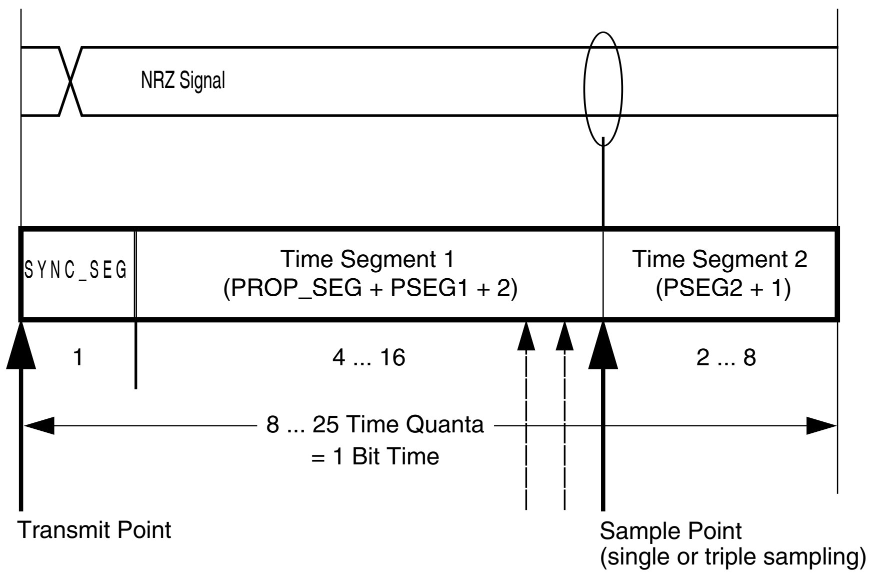

Figure 46-273. Segments within the bit time

Whenever CAN bit is used as a measure of duration (e.g. MCR[FRZACK] and MCR[LPMACK]), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRESDIV + 1)}{f_{CANCLK}}$$

where:

- NCCP is the number of peripheral clocks in one CAN bit;
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CTRL1[PSEG1] field;
- PSEG2 is the value in CTRL1[PSEG2] field;

- PROPSEG is the value in CTRL1[PROPSEG] field;
- PRESDIV is the value in CTRL1[PRESDIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

Table 46-292. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives an overview of the CAN compliant segment settings and the related parameter values.

Table 46-293. CAN standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN standard. For bit time calculations, use an IPT (Information Processing Time) of 2, which is the value implemented in the FlexCAN module.

46.4.8.5 Arbitration and matching timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

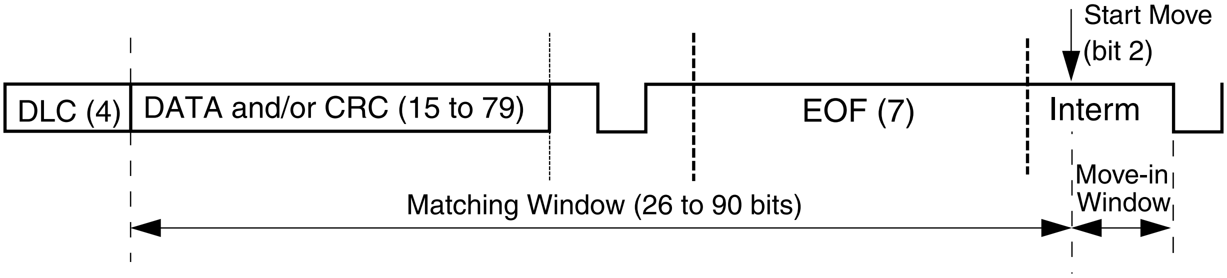

Figure 46-274. Matching and move-in time windows

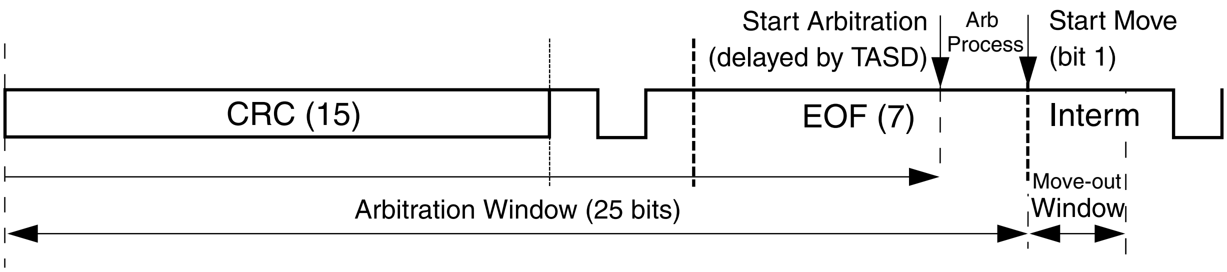

Figure 46-275. Arbitration and move-out time windows

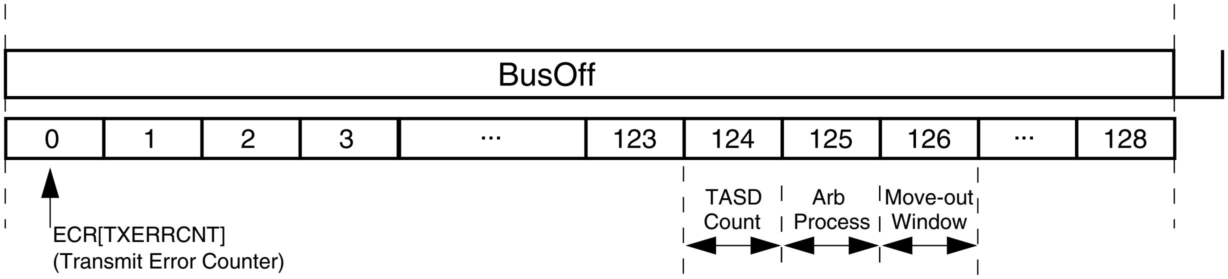

Figure 46-276. Arbitration at the end of bus off and move-out time windows

NOTE

The matching and arbitration timing shown in the preceding figures do not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in Table 46-293
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, that is, the PLL can not be programmed to divide down the oscillator clock; see Clock domains and restrictions
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table:

Table 46-294. Minimum ratio between peripheral clock frequency and CAN bit rate

Number of Message Buffers	RFEN	Minimum number of peripheral clocks per CAN bit
16 and 32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, therefore the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in the preceding table can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRESDIV, PROPSEG, PSEG1, PSEG2) contained in the Control 1 Register (CTRL1).

In case of synchronous operation (when the peripheral clock frequency is equal to the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by selecting an adequate value for PRESDIV in order to meet the requirement in the preceding table. In case of asynchronous operation (the peripheral clock frequency greater than the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by both PRESDIV and/or the frequency ratio.

As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRESDIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

46.4.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator domain clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

46.4.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

“Permanent Dominant” failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a “Permanent Dominant”, the corresponding acknowledge can never be asserted.

46.4.10.1 Freeze mode

This mode is requested by the CPU through the assertion of the HALT bit in the MCR Register or when the MCU is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in a low-power mode. The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.

- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in MCR

After requesting Freeze mode, the user must wait for the FRZ_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK_SRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the MCR Register
- The MCU is removed from Debug Mode and/or the HALT bit is negated

The FRZ_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

46.4.10.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM_ACK bit in the same register. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM_ACK bit and negates the FRZ_ACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive

- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPM_ACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

46.4.10.3 Stop mode

This is a system low-power mode in which all MCU clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

46.4.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG Registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

Note

> It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (MCR[RFEN] = 1), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag" and bits 4-0 are unused. See the description of the Interrupt Flags 1 Register (IFLAG1) for more information.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Tx Warning and Rx Warning generate interrupts like the MB interrupt sources, and can be read from both the Error and Status Register 1 and 2. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the Control 1 Register.

46.4.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN is configured with 16 MBs, RFFN is 0x0, and MAXMB is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

46.4.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors). Errors in more than 2 bits may not be detected. When read, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

Memory errors are indicated to Host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by ECCDIS bit in Memory Error Control Register (MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations. It assures that memory has consistent parity bits associated to data.

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CTRL2) grants write access to all memory positions from 0x080 to 0xADF.

To avoid that critical error correction configuration be accidentally changed, this protocol must be followed to enable the update of the Memory Error Control Register (MECR):

1. By default, ECRWRE bit in Control 2 Register (CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CTRL2).
3. Clear ECRWRDIS bit.
4. All writes to Memory Error Control Register (MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (MECR) by either setting ECRWRDIS or clearing ECRWRE.

46.4.13.1 Sources of the Memory Access

The FlexCAN memory can be accessed by 2 major sources (or requestors):

- by Host (CPU): largest word accessed is 32-bit wide
- by FlexCAN internals processes (Match, Arbitration, RxMove on reception, TxMove on transmission): largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

46.4.13.2 Error Indication

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separatedly than the ones detected in requests by FlexCAN internal processes. Corrected errors indication makes no distinction of the source of the access. There are 3 independent flags for these 3 cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both non-corrected and corrected errors are found in different bytes in the same read operation both flags are set.

The non-corrected error detected in Host accesses are also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit HANCEIF is not masked, the same non-corrected error will raise a bus transfer error and an interrupt request.

Each indication flag has one Overrun flag in Error Status Register (ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the Interrupt flag
4. If the Overrun flag is active:
   a. Alert application that at least one error could not be handled
   b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

46.4.13.3 Error Reporting

Report registers Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in the “Error Indication” section. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules.

1. If any of the 2 non-corrected error flags is currently set, does not update the registers (preserve the old non-corrected error reporting)
2. Else (no error flag is currently set or only the corrected error flag is currently set), update the report registers according to the new error; or according to the most severe of new errors if non-corrected and corrected errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the semantic described in the “Error Indication” section and in the Error Report Address Register (RERRAR) description.

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. How the reported addresses correspond to locations in the module memory map is shown in the Error Injection Address Register (ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the element accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by clearing the MECR[RERRDIS] bit before reading the report registers.

46.4.13.4 Response to Errors

Correctable errors have no consequence on FlexCAN operation, once the corrected data is used by Host or FlexCAN internal processes. For host-initiated reads, a non-corrected error detected does not affect FlexCAN operation.

Non-corrected errors detected on memory reads requested by FlexCAN do not stop the FlexCAN processing and this may result in incorrect operation.

If a non-corrected error occurs during a reception process (Match or RxMove), an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If a non-corrected error occurs during either an Arbitration or a TxMove process, either a non-highest priority frame may be mistakenly selected to be transmitted or no frame may be transmitted at all, when MECR[NCEFAFRZ] = 1.

The error report registers can provide information to the application for a customized handling of these situations. If the delay of this handling is not accepted and MECR[NCEFAFRZ] = 1, the FlexCAN stops operation automatically and enters Freeze mode when these errors are detected. See the Memory Error Control Register (MECR) description for more details.

46.4.13.5 Error Injection

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. How the error injection addresses correspond to locations in the module memory map is shown in the ERRIAR description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control Register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the HAERRIE and FAERRIE bits in Memory Error Control Register (MECR) must be cleared while configuring the memory injection registers.

46.5 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

46.5.1 FlexCAN initialization sequence

The FlexCAN module may be reset as follows:

- MCU level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See Table 46-2 to see what registers are affected by soft reset.
- MCU level soft reset, which has the same effect as the SOFTRST bit in MCR

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to

know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLKSRC bit) should be selected while the module is in Disable mode. After the clock source is selected and the module is enabled (MDIS bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode; see Freeze mode. The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register
    - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
    - Enable the warning interrupts by setting the WRNEN bit
    - If required, disable frame self reception by setting the SRXDIS bit
    - Enable the Rx FIFO by setting the RFEN bit
    - Enable the abort mechanism by setting the AEN bit
    - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control Register
    - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
    - Determine the bit rate by programming the PRESDIV field
    - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
    - The Control and Status word of all Message Buffers must be initialized
    - If Rx FIFO was enabled, the ID filter table must be initialized
    - Other entries in each Message Buffer should be initialized as required

- Initialize the Rx Individual Mask Registers
- When ECC is enabled, follow the initialization note in Detection and Correction of Memory Errors
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts) and in CTRL Register (for Bus Off and Error interrupts)
- Negate the HALT bit in MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

Chapter 47
Serial Peripheral Interface (SPI)

47.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device.

47.1.1 Block Diagram

The block diagram of this module is as follows:

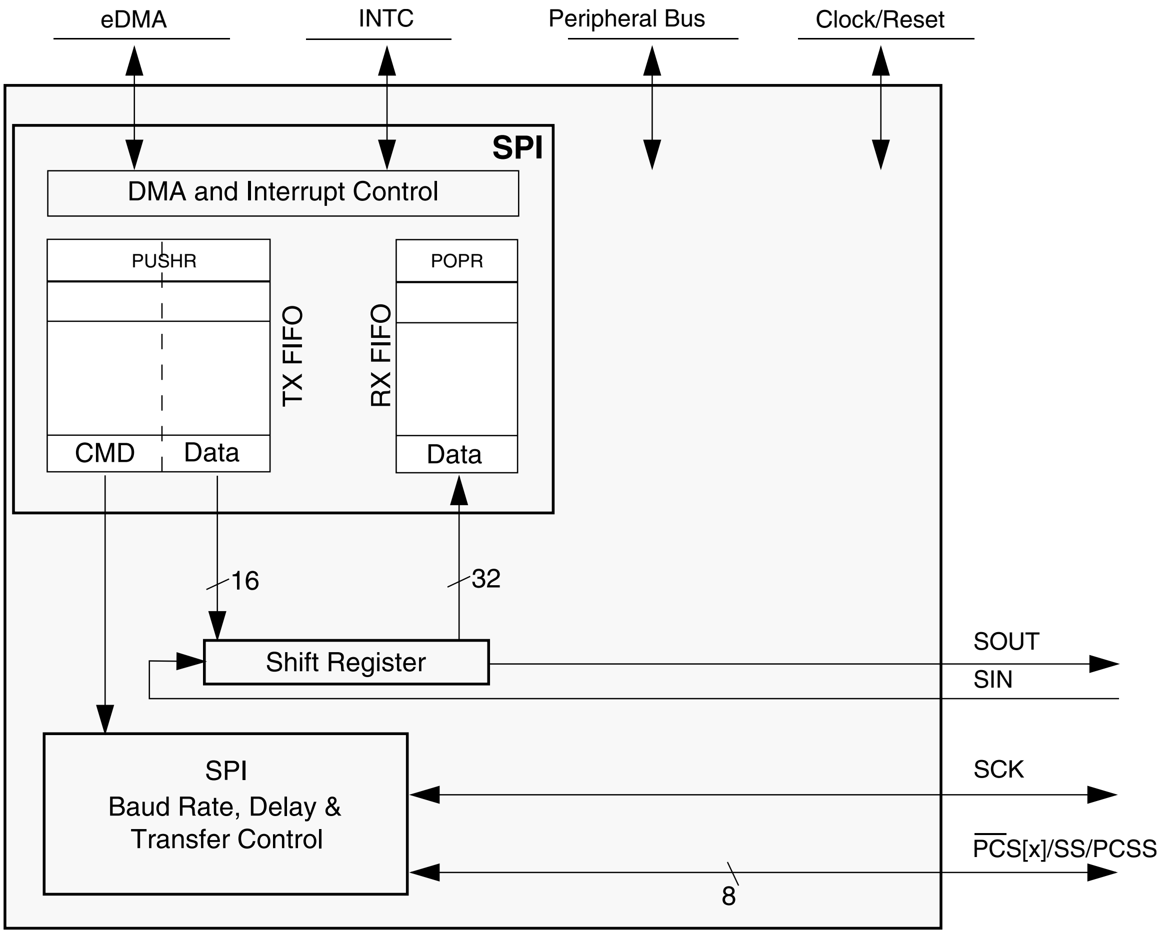

Figure 47-1. SPI Block Diagram

47.1.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master and Slave modes
  - Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of four entries
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of four entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues

- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - four transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size of 4–16 bits, expandable by software control
    - SPI frames longer than 16 bits can be supported using the continuous selection format
  - Continuously held chip select capability
  - Parity control
- 6 peripheral chip selects (PCSs), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 PCS with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - Transfer of current frame complete (TCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
- Global interrupt request line
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
  - Support for Stop mode

47.1.3 SPI Configuration

The SPI configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

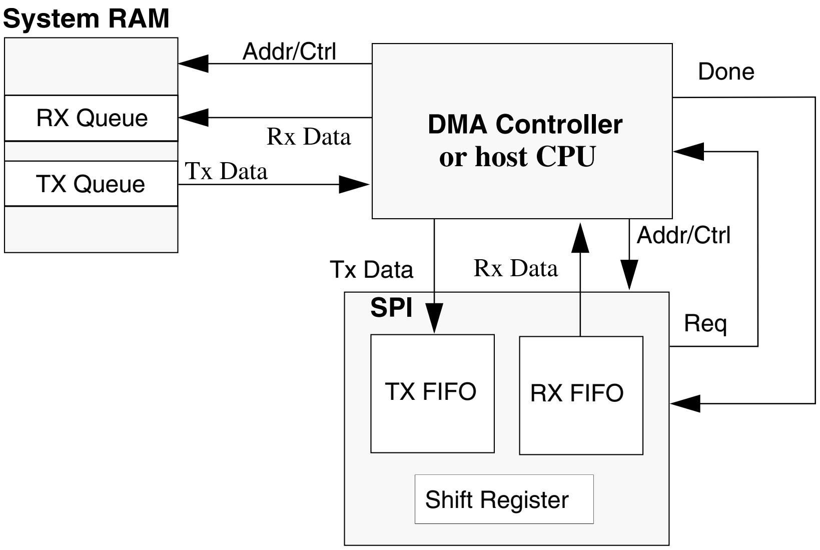

Figure 47-2. SPI with queues and DMA

47.1.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes:

- External Stop mode
- Debug mode

The module enters module-specific modes when the host writes a module register. The MCU-specific modes are controlled by signals external to the module. The MCU-specific modes are modes that an MCU may enter in parallel to the block-specific modes.

47.1.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, the SCK signal, SOUT signal, and the PCS[*x*] signals are controlled by the module and configured as outputs.

47.1.4.2 Slave Mode

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/$\overline{SS}$ signals are configured as inputs and driven by an SPI bus master.

47.1.4.3 Module Disable Mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

47.1.4.4 External Stop Mode

External Stop mode is used for MCU power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the system clock to the module may be shut off.

47.1.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the MCU is in debug mode.
- If the bit is cleared, the MCU debug mode has no effect on the module.

47.2 Module signal descriptions

This section provides description of the module signals.

The following table lists the signals that may connect off chip depending on device implementation.

Table 47-1. Module signal descriptions

Signal	Master Mode	Slave Mode	Port Direction
PCS0/$\overline{\text{SS}}$	Peripheral Chip Select 0 output	Slave Select input	I/O
PCS[3:1]	Peripheral Chip Select 1 – 3	Unused	O
PCS4	Peripheral Chip Select 4	Unused	O
PCS5/ $\overline{\text{PCSS}}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	Unused	O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O
SCK	Master mode: Serial Clock (output)	Serial Clock (input)	I/O

47.2.1 PCS0/$\overline{\text{SS}}$ — Peripheral Chip Select/Slave Select

In Master mode, the PCS0 signal is an output that selects which slave device the current transmission is intended for.

In Slave mode, the active low $\overline{\text{SS}}$ signal is an input signal that allows an SPI master to select the module as the target for transmission.

47.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are output signals in Master mode.

In Slave mode, these signals are unused.

47.2.3 PCS4 — Peripheral Chip Select 4

In Master mode, PCS4 is an output signal.

In Slave mode, this signal is unused.

47.2.4 PCS5/$\overline{\text{PCSS}}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the module is in Master mode and the MCR[PCSSE] bit is cleared, this signal selects the slave device the current transfer is intended for.

When the module is in Master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in Slave mode.

47.2.5 SIN — Serial Input

SIN is a serial data input signal.

NOTE

Serial Data Out output buffers are controller through SIUL, and cannot be controller through the module

47.2.6 SOUT — Serial Output

SOUT is a serial data output signal.

NOTE

Serial Data Out output buffers are controller through SIUL, and cannot be controller through the module.

47.2.7 SCK — Serial Clock

SCK is a serial communication clock signal.

In Master mode, the module generates the SCK.

In Slave mode, SCK is an input from an external bus master.

47.3 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the POPR also results in a transfer error.

SPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4002_C000	Module Configuration Register (SPI0_MCR)	32	R/W	0000_4001h	47.3.1/2534

47.3.1 Module Configuration Register (SPIx_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SPIx_MCR field descriptions

Field	Description
31 MSTR	Master/Slave Mode Select Configures the module for either Master mode or Slave mode. 0 The module is in Slave mode. 1 The module is in Master mode.
30 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously.

Table continues on the next page...

SPIx_MCR field descriptions (continued)

Field	Description
	0 Continuous SCK disabled. 1 Continuous SCK enabled.
29–28 DCONF	SPI Configuration. Selects among the different configurations of the module. 00 SPI 01 Reserved 10 Reserved 11 Reserved
27 FRZ	Freeze Enables the SPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in Debug mode. 1 Halt serial transfers in Debug mode.
26 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
25 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
24 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default

Table continues on the next page...

SPIx_MCR field descriptions (continued)

Field	Description
	reset value of 0. When SPI is used in Slave Mode, it is recommended to leave this bit set to '0', since a slave doesn't have control over master transactions. 0 Enables the module clocks. 1 Allows external logic to disable the module clocks.
13 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared. 0 TX FIFO is enabled. 1 TX FIFO is disabled.
12 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 RX FIFO is enabled. 1 RX FIFO is disabled.
11 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero. 0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.
10 CLR_RXF	Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.
9–8 SMPL_PT	Sample Point Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0. 00 0 system clocks between SCK edge and SIN sample 01 1 system clock between SCK edge and SIN sample 10 2 system clocks between SCK edge and SIN sample 11 Reserved
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHR register. The firmware should select appropriate masks when providing continuous frames via the PUSHR register. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR register.

Table continues on the next page...

SPIx_MCR field descriptions (continued)

Field	Description
1 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
0 HALT	Halt The HALT bit starts and stops SPI transfers. See Start and Stop of Module transfers 0 Start transfers. 1 Stop transfers.

47.3.2 Transfer Count Register (SPIx_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SPIx_TCR field descriptions

Field	Description
31–16 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.3.3 Clock and Transfer Attributes Register (In Master Mode) (SPIx_CTAR*n*)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

When the module is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, the CTAR0 register is used.

Address: Base address + Ch offset + (4d × i), where i=0d to 3d

SPIx_CTAR*n* field descriptions

Field	Description
31 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate.

Table 47-48. SPI SCK Duty Cycle

DBR	CPHA	PBR	SCK Duty Cycle
0	any	any	50/50
1	0	00	50/50
1	0	01	33/66
1	0	10	40/60
1	0	11	43/57
1	1	00	50/50
1	1	01	66/33
1	1	10	60/40
1	1	11	57/43

Table continues on the next page...

SPIx_CTAR*n* field descriptions (continued)

Field	Description
	0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
30–27 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4.
26 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode , the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
24 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
23–22 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer PCS to SCK Delay (t_{CSC}) for more details. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
21–20 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. Refer After SCK Delay (t_{ASC}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.

Table continues on the next page...

SPIx_CTAR*n* field descriptions (continued)

Field	Description
19–18 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer Delay after Transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
17–16 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The system clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
15–12 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the system clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_{SYS}) \times PCSSCK \times CSSCK$. The following table lists the delay scaler values.

Table 47-47. Delay Scaler Encoding

Field Value	Delay Scaler Value

SPIx_CTARn field descriptions (continued)

Field	Description
	Table 47-47. Delay Scaler Encoding (continued) Field Value: 1110 — Delay Scaler Value: 32768 Field Value: 1111 — Delay Scaler Value: 65536 Refer PCS to SCK Delay (t_{CSC}) for more details.
11–8 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the system clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_{SYS}) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer After SCK Delay (t_{ASC}) for more details.
7–4 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the system clock period, and it is computed according to the following equation: $t_{DT} = (1/f_{SYS}) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values.
3–0 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled system clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: SCK baud rate = $(f_{SYS} /PBR) \times [(1+DBR)/BR]$ The following table lists the baud rate scaler values.

Table 47-46. Baud Rate Scaler

SPIx_CTAR*n*_SLAVE field descriptions

Field	Description
31–27 FMSZ	Frame Size The number of bits transfered per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.
26 CPOL	Clock Polarity

Table continues on the next page...

SPIx_CTAR*n*_SLAVE field descriptions (continued)

Field	Description
	Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode , the bit value is ignored and the transfers are done as the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
24 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
23 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.3.5 Status Register (SPIx_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: Base address + 2Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SPIx_SR field descriptions

Field	Description
31 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it. 0 Transfer not complete. 1 Transfer complete.
30 TXRXS	TX and RX Status Reflects the run status of the module.

Table continues on the next page...

SPIx_SR field descriptions (continued)

Field	Description
	0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
27 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for SPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it. 0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 TFFF	Transmit FIFO Fill Flag Provides a method for the module to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 TX FIFO is full. 1 TX FIFO is not full.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 SPEF	SPI Parity Error Flag Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it.

Table continues on the next page...

SPIx_SR field descriptions (continued)

Field	Description
	0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 RFDF	Receive FIFO Drain Flag Provides a method for the module to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by acknowledgement from the DMA controller when the RX FIFO is empty. 0 RX FIFO is empty. 1 This bit auto-clears on every RXFR read performed.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
11–8 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
7–4 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
3–0 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

47.3.6 DMA/Interrupt Request Select and Enable Register (SPIx_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: Base address + 30h offset

13–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.3.7 PUSH TX FIFO Register In Master Mode (SPIx_PUSHR)

PUSHR provides the means to write to the TX FIFO . Data written to this register is transferred to the TX FIFO 8- or 16-bit write accesses to the PUSHR transfer all 32 register bits to the TXFIFO.The register structure is different in Master and Slave modes. In Master mode, the register provides 16-bit command and data to the TX FIFO. In Slave mode, all 32 register bits can be used as data, supporting up to 32-bit SPI Frame operation.

A PUSHR Read Operation returns the topmost TX FIFO entry.

When the module is disabled, any writes to this register will not update the FIFO. Hence any reads performed during Module disable mode will return the last PUSHR write performed when Module was enabled.

SPIx_PUSHR field descriptions

Field	Description
31 CONT	Continuous Peripheral Chip Select Enable

Table continues on the next page...

SPIx_PUSHR field descriptions (continued)

Field	Description
	Selects a continuous selection format. The bit is used in SPI Master mode. The bit enables the selected PCS signals to remain asserted between transfers. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
30–28 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI Slave mode, CTAR0 is used. See the chapter on chip configuration to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0 001 CTAR1 010 CTAR2 011 CTAR3 100 Reserved 101 Reserved 110 Reserved 111 Reserved
27 EOQ	End Of Queue Host software uses this bit to signal to the module that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
26 CTCNT	Clear Transfer Counter Clears the TCNT field in the TCR register. The TCNT field is cleared before the module starts transmitting the current SPI frame. 0 Do not clear the TCR[TCNT] field. 1 Clear the TCR[TCNT] field.
25 PE_MASC	Parity Enable or Mask T_{ASC} delay in the current frame PE – This bit enables parity bit transmission and parity reception check for the SPI frame. MASC - The current frame has the “after SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE:** This bit is used as Mask T_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE - No parity bit included/checked. MASC - T_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - T_{ASC} delay is masked in the current frame.
24 PP_MCSC	Parity Polarity or Mask T_{CSC} delay in the next frame PP - It controls the polarity of the parity bit transmitted and checked. MCSC - The next frame has the “PCS to SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details.

Table continues on the next page...

SPIx_PUSHR field descriptions (continued)

Field	Description
	NOTE: This bit is used as Mask T_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC - T_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC - T_{CSC} delay is masked in the next frame.
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip configuration chapter for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
15–0 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

47.3.8 PUSH TX FIFO Register In Slave Mode (SPIx_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO. Data written to this register is transferred to the TX FIFO. 8- or 16-bit write accesses to the PUSHR transfer all 32 register bits to the TXFIFO.The register structure is different in master and slave modes. In master mode the register provides 16-bit command and data to the TX FIFO. In slave mode, all 32 register bits can be used as data, supporting up to 32-bit SPI Frame operation.

Field	Description
31–0 RXDATA	Receive Data Contains the received SPI data.

47.4 Functional description

The Serial Peripheral Interface (SPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The SPI has the following configurations

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPIx_MCR is 0b00.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See Clock and Transfer Attributes Register (In Master Mode) (SPI_CTAR*n*) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

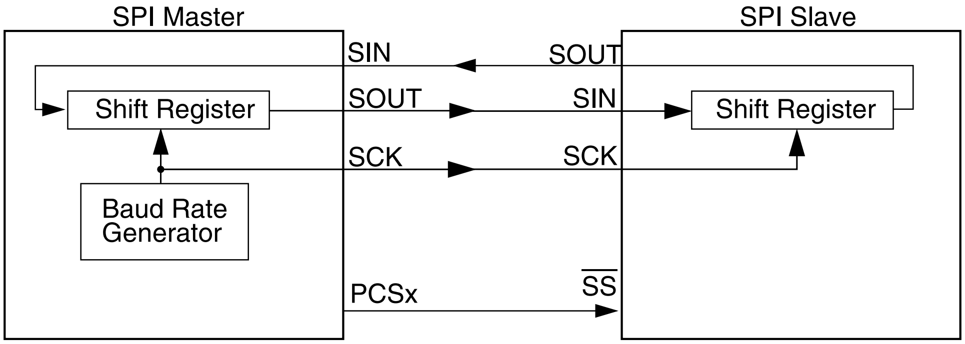

Figure 47-123. SPI serial protocol overview

Generally, more than one slave device can be connected to the module master. Six Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip configuration chapter for the number of PCS signals used in this MCU.

The SPI configuration share transfer protocol and timing properties which are described independently of the configuration in Transfer formats . The transfer rate and delay settings are described in Module baud rate and clock delay generation.

47.4.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear

- MCU is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

47.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to SPI RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in Transmit First In First Out (TX FIFO) buffering mechanism, Transmit First In First Out (TX FIFO) buffering mechanism and Receive First In First Out (RX FIFO) buffering mechanism. The interrupt and DMA request conditions are described in Interrupts/DMA requests.

The SPI configuration supports two block-specific modes—Master mode and Slave mode.In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

47.4.2.1 Master mode

In SPI Master, mode the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert . The command field also contains various bits that help with queue management and transfer protocol . See PUSH TX FIFO Register In Master Mode (SPI_PUSHR) for details on the SPI command fields.

The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

47.4.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0 . The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

47.4.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately; setting the MCR[DIS_TXF] bit disables the TX FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO is disabled, the fields SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO but the contents of TXFRs, SR[TXNXTPTR] are undefined. Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

47.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds four words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to the Data Field of SPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

47.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See Transmit FIFO Fill Interrupt or DMA Request for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

47.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See Transmit FIFO Underflow Interrupt Request for details.

47.4.2.5 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from

the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

47.4.2.5.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

47.4.2.5.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

47.4.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

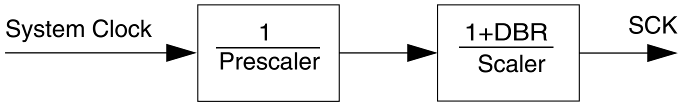

Figure 47-124. Communications clock prescalers and scalers

47.4.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The system clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 47-202. Baud rate computation example

f_{SYS}	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

47.4.3.2 PCS to SCK Delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See Figure 47-126 for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*x* registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 47-203. PCS to SCK delay computation example

f_{SYS}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 μs

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

47.4.3.3 After SCK Delay (t_{ASC})

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See Figure 47-126 and Figure 47-127 for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR*x* registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 47-204. After SCK Delay computation example

f_{SYS}	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 μs

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

47.4.3.4 Delay after Transfer (t_{DT})

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See Figure 47-126 for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR*x* registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

Table 47-205. Delay after Transfer computation example

f_{SYS}	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

47.4.3.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The $\overline{\text{PCSS}}$ signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode the PCS[0] – PCS[4] signals into as many as 128 glitch-free PCS signals. The following figure shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

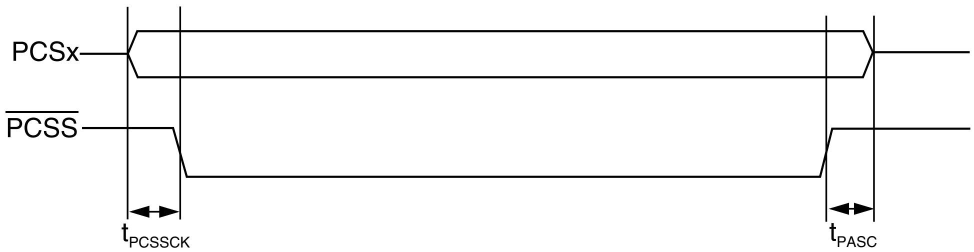

Figure 47-125. Peripheral Chip Select Strobe timing

The delay between the assertion of the PCS signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{SYS}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{SYS}}} \times \text{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 47-206. Peripheral Chip Select Strobe Assert computation example

f_{SYS}	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 47-207. Peripheral Chip Select Strobe Negate computation example

f_{SYS}	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The $\overline{\text{PCSS}}$ signal is not supported when Continuous Serial Communication SCK mode is enabled.

NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

47.4.4 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI configurations, the module provides the option of keeping the PCS signals asserted between frames. See Continuous Selection Format for details.

47.4.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

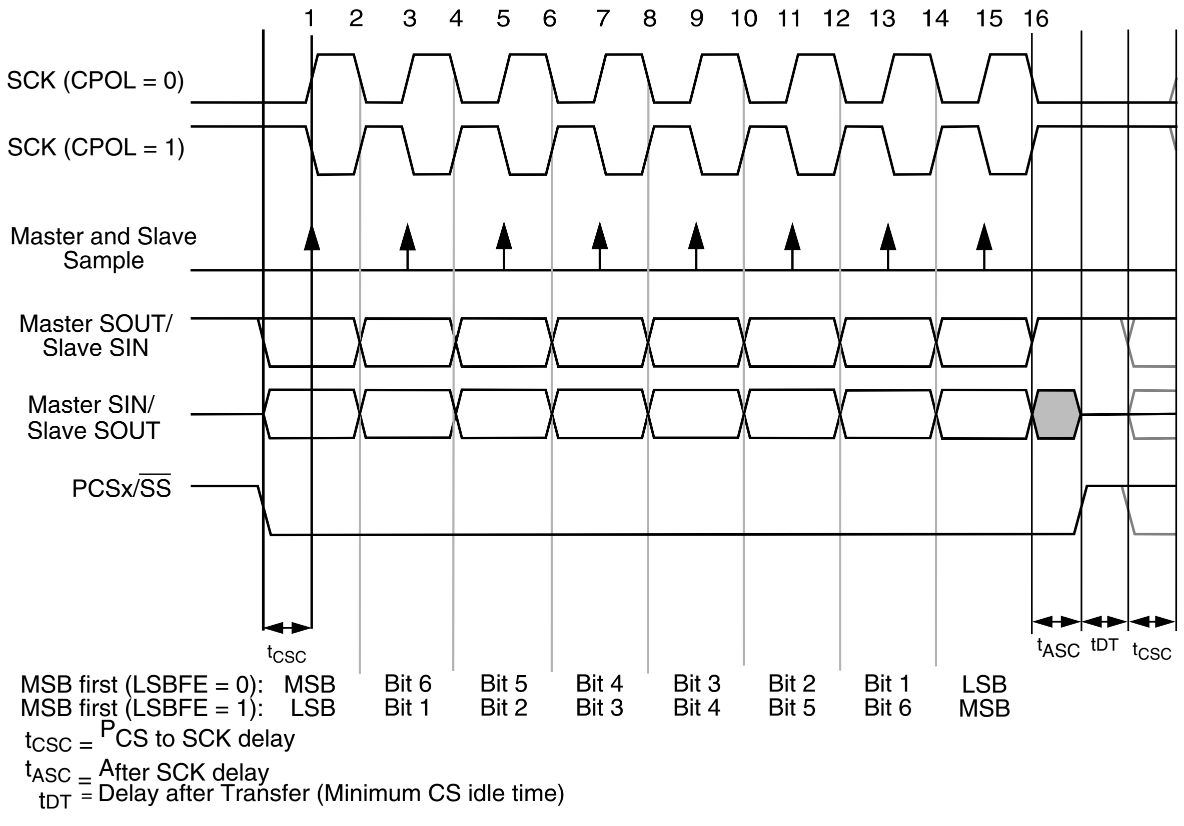

Figure 47-126. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{ASC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and

slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

47.4.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges .

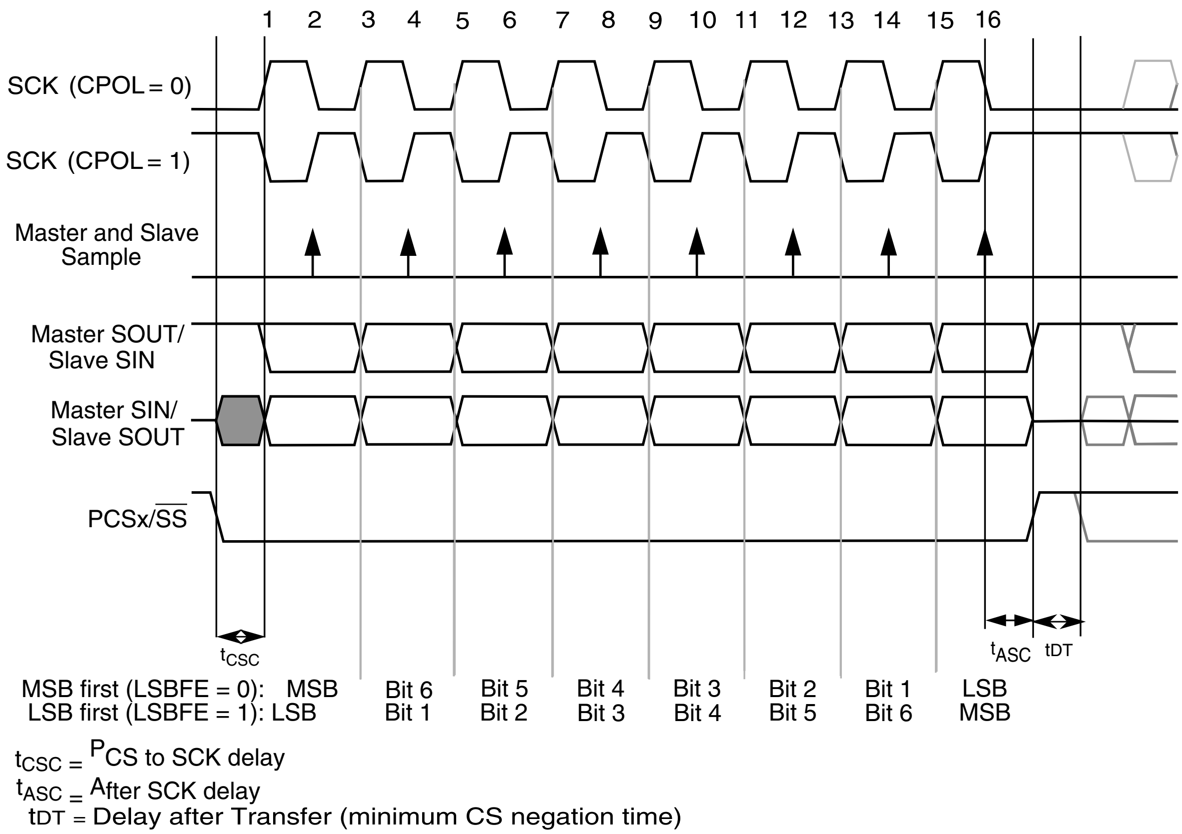

Figure 47-127. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin .The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

47.4.4.3 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command. The behavior of the PCS signals in the configurations is identical so only SPI configuration will be described.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

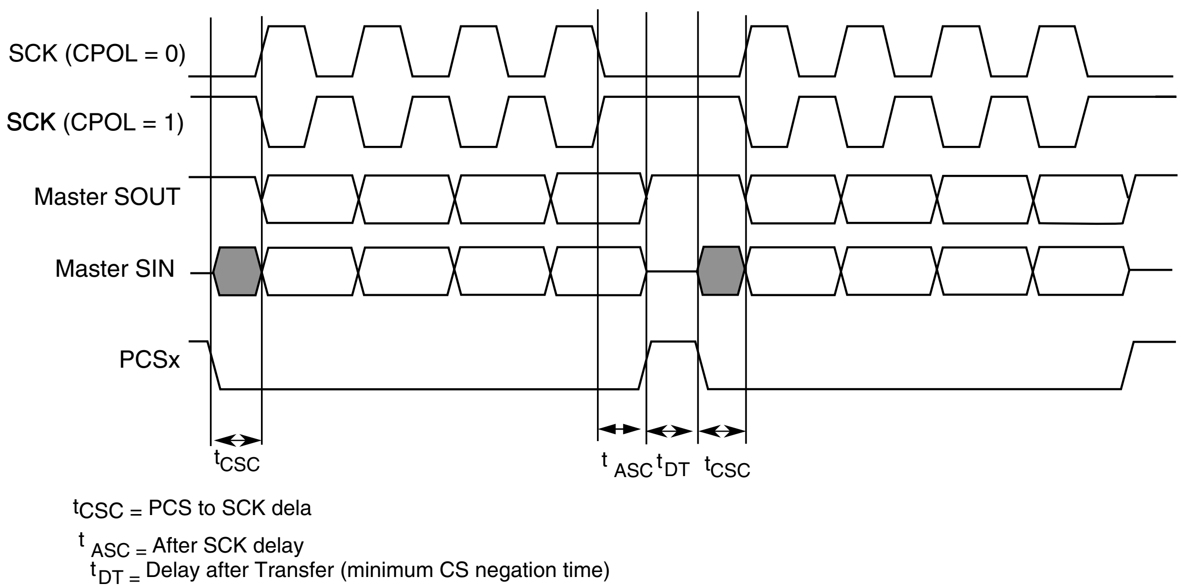

Figure 47-128. Example of non-continuous format (CPHA=1, CONT=0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

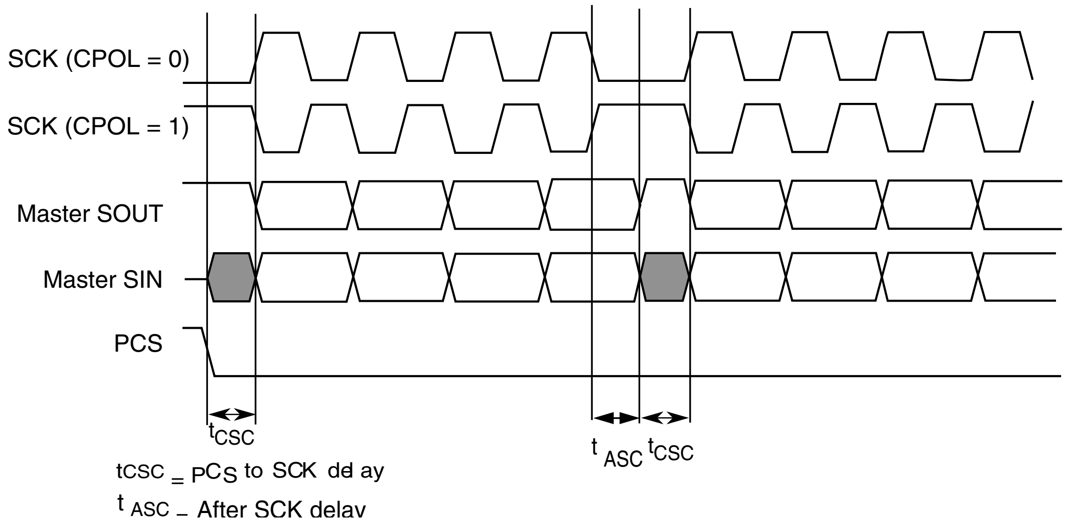

Figure 47-129. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.
- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- The PUSHR[CONT] bits must be deasserted before asserting MCR[HALT] bit in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

47.4.4.4 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

NOTE

The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR register. When this bit is asserted, MASC and MCSC bits of the PUSHR register perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and to speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR register.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.

- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here too.

The following figure shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

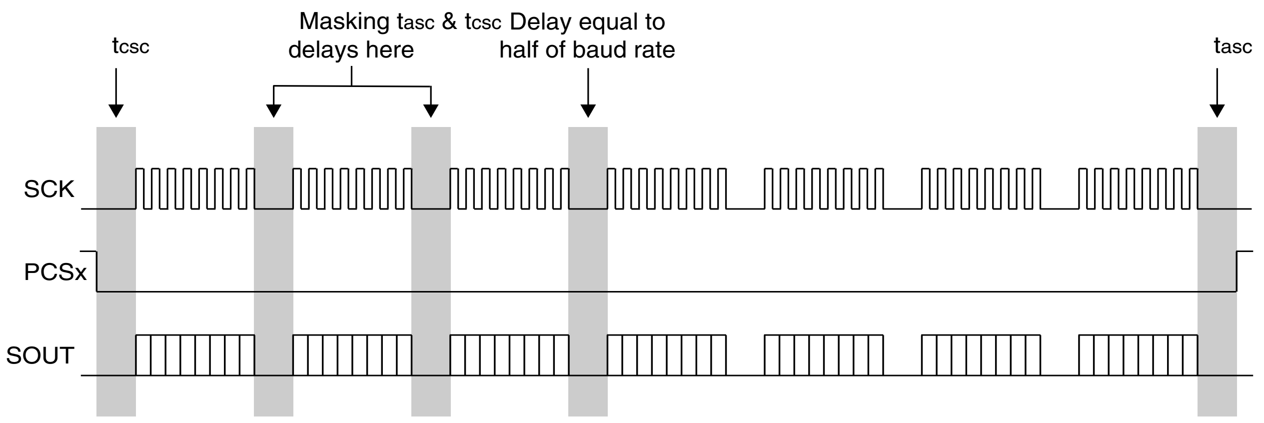

Figure 47-130. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

47.4.5 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

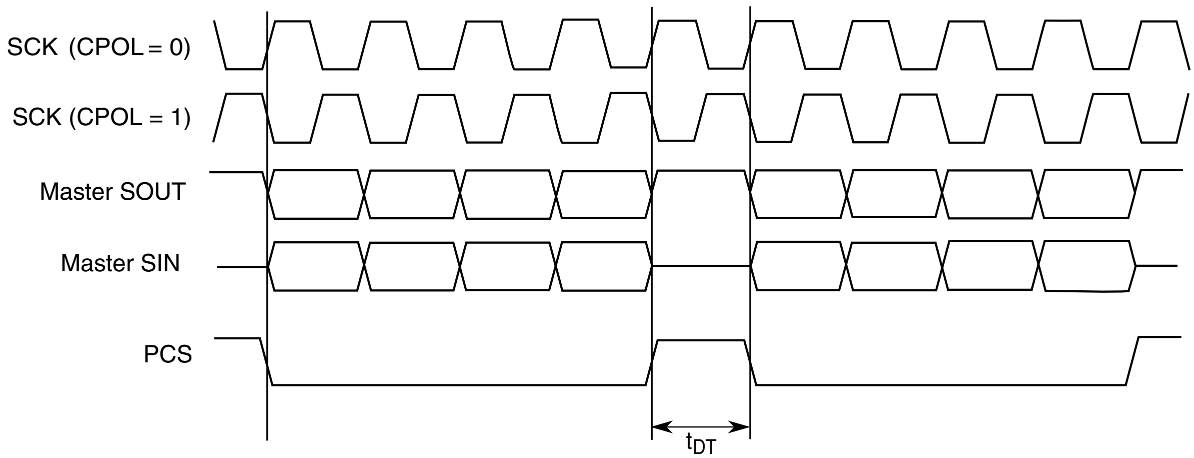

Figure 47-131. Continuous SCK Timing Diagram (CONT=0)

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.

- Continuous SCK with CONT bit set and entering Stopped state (refer to Start and Stop of module transfers).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

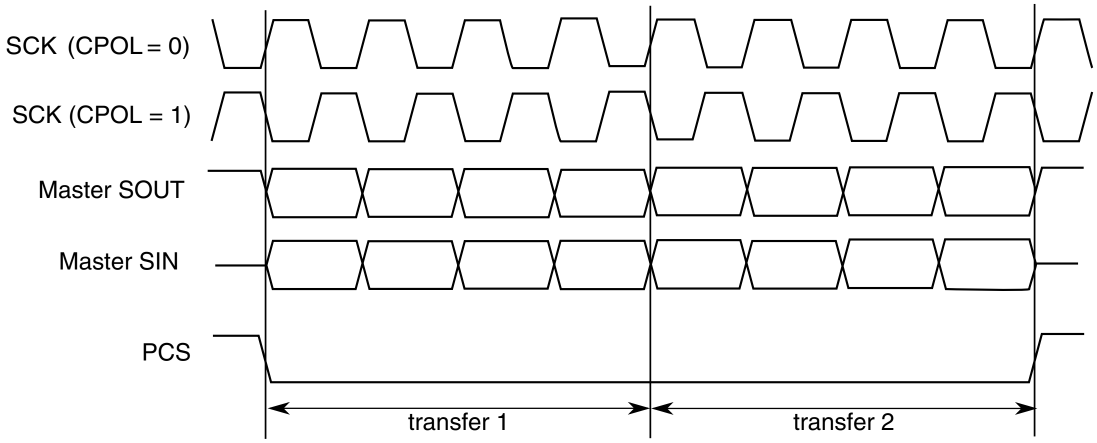

Figure 47-132. Continuous SCK timing diagram (CONT=1)

47.4.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the SPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and $\overline{SS}$ signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

47.4.7 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/

control is done on frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop SPI frame transmission in case of a frame reception with parity error.

47.4.7.1 Parity for SPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

47.4.8 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 47-208. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
Transfer Complete	TCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

47.4.8.1 End of Queue Interrupt Request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

NOTE

This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

47.4.8.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

47.4.8.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

47.4.8.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration . The TFUF bit is set when the TX FIFO of a SPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

47.4.8.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

47.4.8.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

47.4.8.7 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

47.4.9 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

47.4.9.1 Stop mode (External Stop mode)

The SPI supports the Stop mode protocol. When a request is made to enter External Stop mode, the SPI block acknowledges the request . If a serial transfer is in progress, the SPI waits until it reaches the frame boundary before it is ready to have its clocks shut off . While the clocks are shut off, the SPI memory-mapped logic is not accessible. This also puts the SPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

47.4.9.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state.If implemented, the Clock Enable signal can stop the

clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

47.5 Initialization/application information

This section describes how to initialize the module.

47.5.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues

8. Flush TX FIFO by writing a 1 to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

47.5.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

47.5.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

47.5.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz system frequency and the double baud rate DBR bit is cleared.

Table 47-209. Baud rate values (bps)

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

47.5.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz system frequency.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

Table 47-210. Delay values

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 μs
	32	320.0 ns	960.0 ns	1.6 μs	2.2 μs
	64	640.0 ns	1.9 μs	3.2 μs	4.5 μs
	128	1.3 μs	3.8 μs	6.4 μs	9.0 μs
	256	2.6 μs	7.7 μs	12.8 μs	17.9 μs
	512	5.1 μs	15.4 μs	25.6 μs	35.8 μs
	1024	10.2 μs	30.7 μs	51.2 μs	71.7 μs
	2048	20.5 μs	61.4 μs	102.4 μs	143.4 μs
	4096	41.0 μs	122.9 μs	204.8 μs	286.7 μs
	8192	81.9 μs	245.8 μs	409.6 μs	573.4 μs
	16384	163.8 μs	491.5 μs	819.2 μs	1.1 ms
	32768	327.7 μs	983.0 μs	1.6 ms	2.3 ms
	65536	655.4 μs	2.0 ms	3.3 ms	4.6 ms

47.5.6 Calculation of FIFO pointer addresses

Complete visibility of the TX and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over to the RX FIFO. See Transmit First In First Out (TX FIFO) buffering mechanism and Receive First In First Out (RX FIFO) buffering mechanism for details on the FIFO operation.

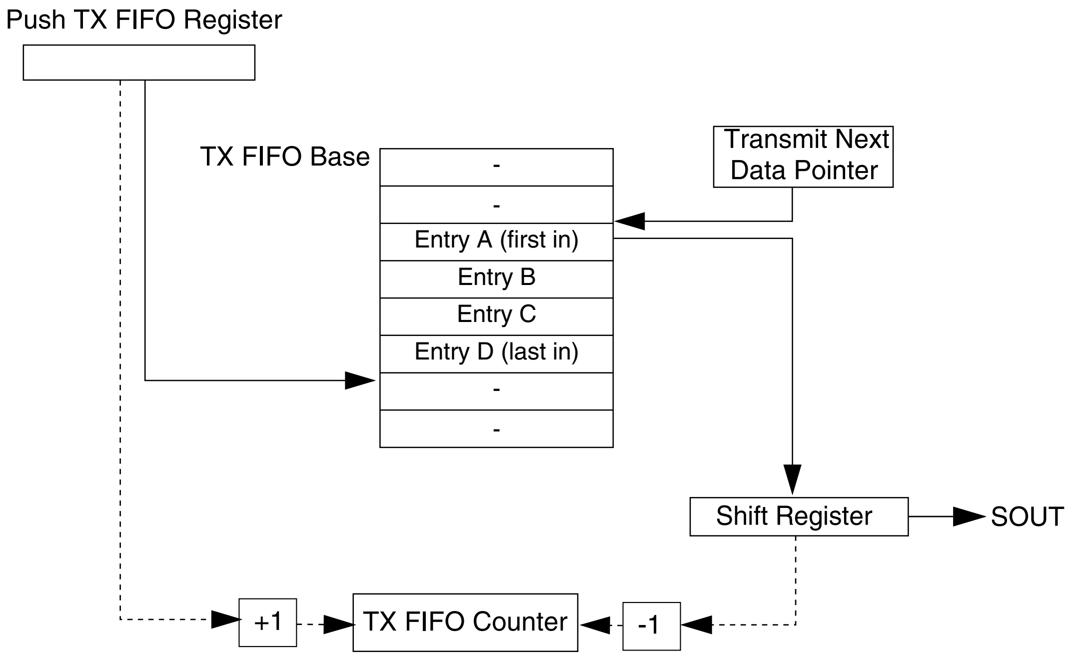

Figure 47-133. TX FIFO pointers and counter

47.5.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1)\text{mod}(\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO
TXCTR - TX FIFO Counter
TXNXTPTR - Transmit Next Pointer
TX FIFO Depth - Transmit FIFO depth, implementation specific

47.5.6.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \text{mod} (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO
RXCTR - RX FIFO counter
POPNXTPTR - Pop Next Pointer
RX FIFO Depth - Receive FIFO depth, implementation specific

Chapter 48
Inter-Integrated Circuit (I2C)

48.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- Introduction to I^2C
- External signal descriptions
- Memory map and register definition
- Functional description
- Initialization/application information

48.2 Introduction to I^2C

This section presents the following topics:

- Definition: I^2C module
- Advantages of the I^2C bus
- Module block diagram
- Features
- Modes of operation
- Definition: I^2C conditions

48.2.1 Definition: I²C module

The I²C module is a functional unit that provides a two-wire— serial data (SDA) and serial clock (SCL) — bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

48.2.2 Advantages of the I²C bus

The synchronous, multiple-master two-wire I²C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

48.2.3 Module block diagram

The following figure shows a block diagram of the I²C module.

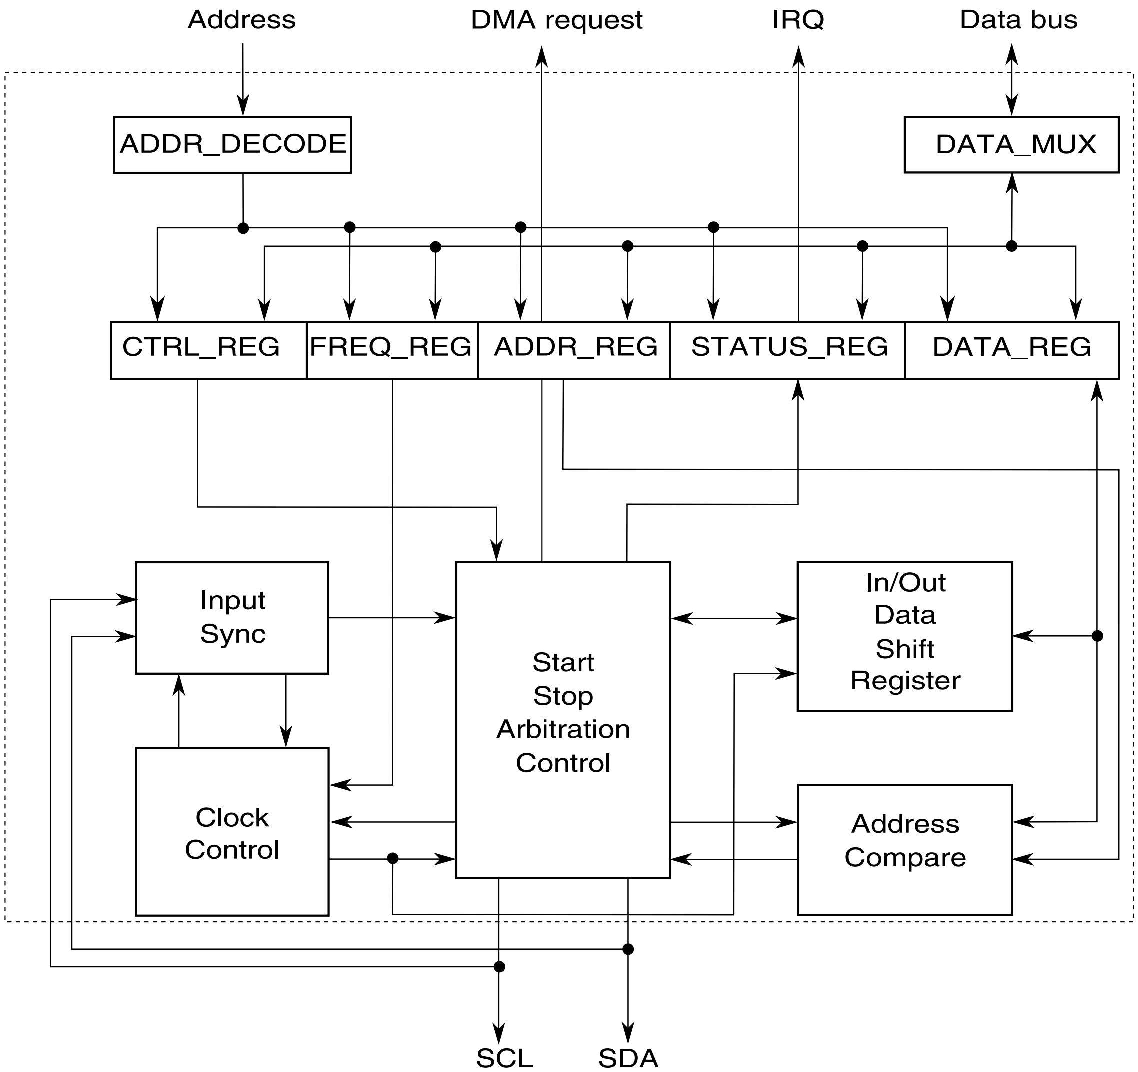

Figure 48-1. I²C block diagram

48.2.4 Features

The I²C module has the following key features:

- Compatible with I²C bus standard[1]
- Operating speeds
  - Up to 100kbps in Standard Mode
  - Up to 400kbps in Fast Mode

1. Compliant with I²C 2.0 standard with the exception that HS (high speed) mode is not supported

    - Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
    - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400pF

48.2.5 Modes of operation

The I^2C module supports the chip modes described in the following table.

Table 48-1. Chip modes supported by the I^2C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn of all the clocks to the I^2C module	The I^2C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus.
IPG DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See IPG DEBUG mode.

In addition to chip modes, the I2C module has several module-specific modes. These are described in the following table.

Table 48-2. Module-specific modes supported by the I²C module

Module mode	Description	Important notes
Master mode	The I²C module is the driver of the SDA line.	• Do not use the I²C module's slave address as a calling address. • The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I²C module is not the driver of the SDA line.	• Enable the I²C module before a START condition from a non-I²C master is detected. • By default the I²C module performs as a slave receiver.

48.2.6 Definition: I²C conditions

The following table shows the I²C-specific conditions defined for the I²C module.

Table 48-3. I²C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in the following figure.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in the following figure.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

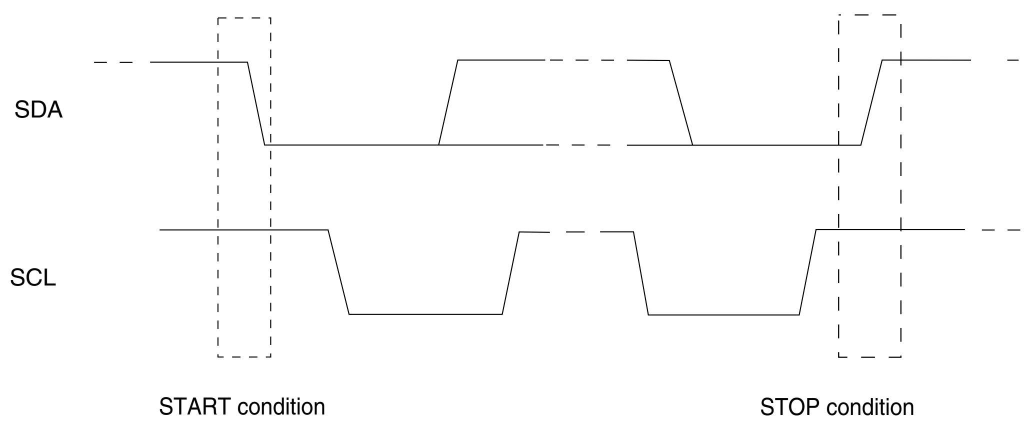

Figure 48-2. START and STOP conditions

48.3 External signal descriptions

This section presents the following topics:

- Signal overview
- Detailed external signal descriptions

48.3.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

48.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in the following table.

Table 48-4. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

48.4 Memory map and register definition

48.4.1 Register accessibility

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

48.4.2 Register figure conventions

The register figures show the field structure using the conventions in the following figure.

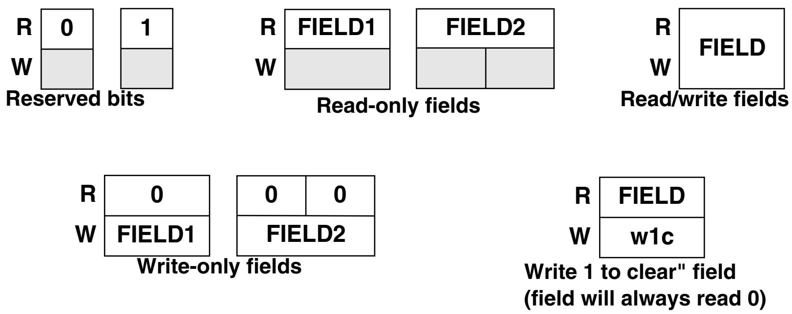

Figure 48-3. Register figure convention

The memory map for the I^{2}C module is given below. The total address for each register is the sum of the base address for the I^{2}C module and the address offset for each register.

I2C memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_6000	I2C Bus Address Register (I2C0_IBAD)	8	R/W	00h	48.4.3/2588
4006_6001	I2C Bus Frequency Divider Register (I2C0_IBFD)	8	R/W	00h	48.4.4/2589

48.4.3 I2C Bus Address Register (I2Cx_IBAD)

This register contains the address the I^{2}C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Address: Base address + 0h offset

Bit	7	6	5	4	3	2	1	0
Read	ADR							0
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_IBAD field descriptions

Field	Description
7–1 ADR	Slave Address. Specific slave address to be used by the I^{2}C Bus module. **NOTE:** The default mode of I^{2}C Bus is slave mode for an address match on the bus.

Table continues on the next page...

I2Cx_IBAD field descriptions (continued)

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.4 I2C Bus Frequency Divider Register (I2Cx_IBFD)

Address: Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read Write	IBC							
Reset	0	0	0	0	0	0	0	0

I2Cx_IBFD field descriptions

Field	Description
7–0 IBC	I-Bus Clock Rate. This field is used to prescale the clock for bit rate selection. The bit clock generator is implemented as a prescale divider. The IBC bits are decoded to give the Tap and Prescale values as follows: 0-1 Selects the prescaled shift register (see Clock rate and IBFD settings) 2-4 Selects the prescaler divider (see Clock rate and IBFD settings) 5-7 Selects the shift register tap point (see Clock rate and IBFD settings)

48.4.5 I2C Bus Control Register (I2Cx_IBCR)

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	0
Write						RSTA		
Reset	1	0	0	0	0	0	0	0

I2Cx_IBCR field descriptions

Field	Description
7 MDIS	Module disable. This bit controls the software reset of the entire I2C Bus module. **NOTE:** If the I2C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I2C Bus module losing arbitration, after which, bus operation would return to normal.

Table continues on the next page...

I2Cx_IBCR field descriptions (continued)

Field	Description
	0 The I^2C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled.
6 IBIE	I-Bus Interrupt Enable. 0 Interrupts from the I^2C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I^2C Bus module are enabled. An I^2C Bus interrupt occurs provided the IBIF bit in the status register is also set.
5 MSSL	Master/Slave mode select. When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave Mode 1 Master Mode
4 TXRX	Transmit/Receive mode select. This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit
3 NOACK	Data Acknowledge disable. This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I^2C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **NOTE:** Values written to this bit are only used when the I^2C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data 1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)
2 RSTA	Repeat Start. Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect 1 Generate repeat start cycle
1 DMAEN	DMA Enable. When this bit is set, the DMA Tx and Rx lines will be asserted when the I^2C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I^2C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.6 I2C Bus Status Register (I2Cx_IBSR)

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0
Read	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
Write				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

I2Cx_IBSR field descriptions

Field	Description
7 TCF	Transfer complete. While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **NOTE:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
6 IAAS	Addressed as a slave. When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
5 IBB	Bus busy. This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 0 Bus is Idle 1 Bus is busy
4 IBAL	Arbitration Lost. The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: • SDA is sampled low when the master drives a high during an address or data transmit cycle. • SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 SRW	Slave Read/Write. When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By

Table continues on the next page...

I2Cx_IBSR field descriptions (continued)

Field	Description
	reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IBIF	I-Bus Interrupt Flag. The IBIF bit is set when one of the following conditions occurs: • Arbitration lost (IBAL bit set) • Byte transfer complete (TCF bit set and DMAEN bit not set) • Addressed as slave (IAAS bit set) • NoAck from Slave (MS & Tx bits set) • I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
0 RXAK	Received Acknowledge. This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

48.4.7 I2C Bus Data I/O Register (I2Cx_IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

NOTE

The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/ $\overline{W}$ bit (in position D0).

Address: Base address + 4h offset

48.4.8 I2C Bus Interrupt Config Register (I2Cx_IBIC)

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	BIIE	0			0	0	0	0
Write								
Reset	0	0	0	0	0	0	0	0

I2Cx_IBIC field descriptions

Field	Description
7 BIIE	Bus Idle Interrupt Enable bit. This config bit can be used to enable the generation of an interrupt once the I^{2}C bus becomes idle. Once this bit is set, an IBB high-low transition will set the IBIF bit. This feature can be used to signal to the CPU the completion of a STOP on the I^{2}C bus. 0 Bus Idle Interrupts disabled 1 Bus Idle Interrupts enabled
6–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.9 I2C Bus Debug Register (I2Cx_IBDBG)

Address: Base address + 6h offset

Bit	7	6	5	4
Read	0			
Write				
Reset	0	0	0	0

Bit	3	2	1	0
Read	0		IPG_DEBUG_HALTED	IPG_DEBUG_EN
Write				
Reset	0	0	0	0

I2Cx_IBDBG field descriptions

Field	Description
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 IPG_DEBUG_ HALTED	Debug Halted Bit: This is s status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode
0 IPG_DEBUG_EN	Debug enable bit. This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. **NOTE:** If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited. 0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode

48.5 Functional description

This section presents the following topics:

- Notes about module operation
- Transactions
- Arbitration procedure
- Clock behavior
- Interrupts

- IPG DEBUG mode
- DMA interface

48.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

48.5.2 Transactions

This section presents the following topics:

- Protocol overview
- Transaction protocol definitions
- High-level protocol steps
- START condition
- Slave address transmission
- Data transmission
- STOP condition
- Repeated START condition

48.5.2.1 Protocol overview

The following figure shows the behavior of SCL and SDA during a typical I^2C transaction.

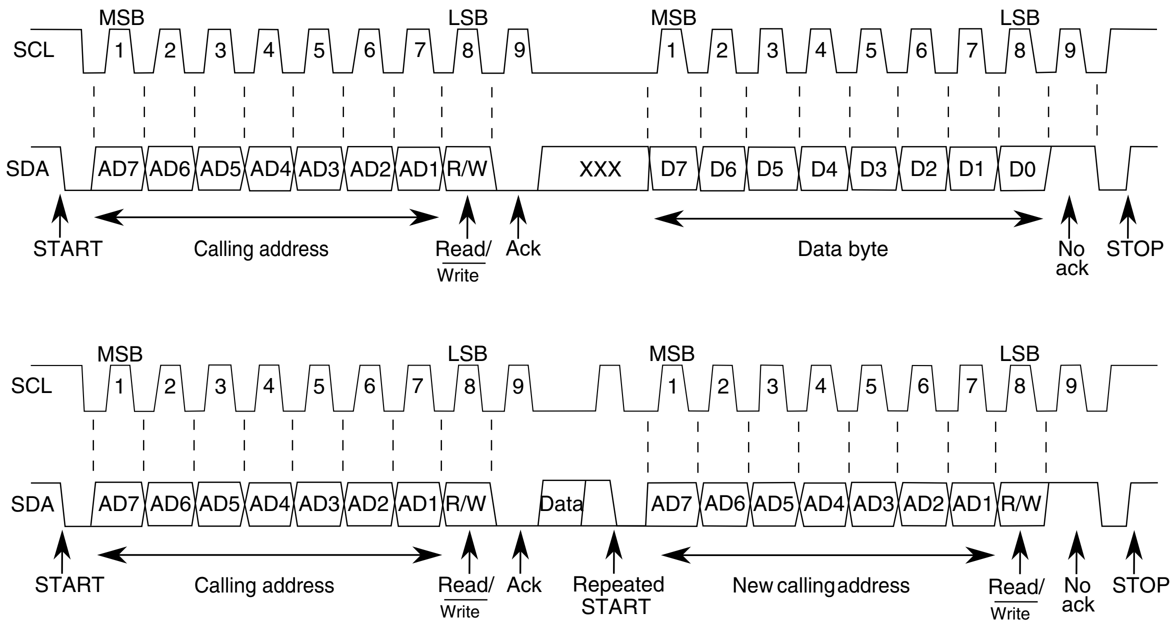

Figure 48-39. I²C transaction protocol

48.5.2.2 Transaction protocol definitions

This section defines several important terms presented in Figure 48-39.

Table 48-45. I²C definitions

Term	Definition
START	A START condition, as defined in Section 1.2.6, Definition: I²C conditions"
STOP	A STOP condition, as defined in Section 1.2.6, Definition: I²C conditions"
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in Section 1.5.2.3, I²C calling address requirements."
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: • 0=The data is being transferred from the master to the slave ("write") • 1=The data is being transferred from the slave to the master ("read")
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

48.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

48.5.2.4 High-level protocol steps

The I^2C protocol conceptually supports two types of transfers, which are illustrated in Figure 48-39. The significant steps in these transfers are presented in the following table. Details of each of these steps are presented in subsequent sections.

Table 48-46. I^2C high-level protocol steps

Standard Transfer	Repeated START Transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Acknowledgment from slave	3. Acknowledgment from slave
4. Data transfer	4. Data transfer
5. STOP condition	5. Repeated START condition
6. (repeat Steps 1–4)	6. (repeat Steps 2–4 as needed)
	7. STOP condition.
	8. (repeat Steps 1–7)

48.5.2.5 START condition

When the bus is free, that is, no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (see Definition: I^2C conditions). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

48.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (see START condition). The process of slave address transmission is presented in the following table.

Table 48-47. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: • The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. • The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

48.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

48.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see Definition: I^{2}C conditions). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see Repeated START condition.

48.5.2.9 Repeated START condition

The I^{2}C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of Figure 48-39.

48.5.3 Arbitration procedure

The I^{2}C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic "1" while another master transmits logic "0". The losing masters immediately switch over to slave receive mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

48.5.4 Clock behavior

This section presents the following topics:

- Clock synchronization
- Clock stretching

- Handshaking
- Clock rate and IBFD settings

48.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached.

However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see the following figure). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

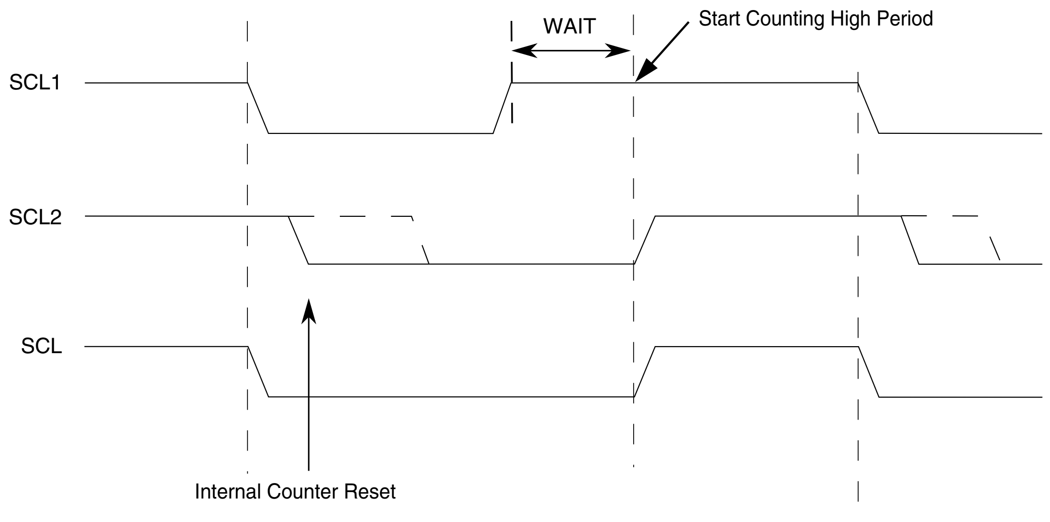

Figure 48-40. I²C bus clock synchronization

48.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

48.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

48.5.4.4 Clock rate and IBFD settings

The following tables describe the settings of several fields in the IBFD register (see I2C Bus Frequency Divider Register (I2C_IBFD)).

Table 48-48. I-Bus multiplier factor

IBC[7-6]	MUL
00	01
01	02
10	04
11	Reserved

Table 48-49. I-Bus prescaler divider values

IBC[5-3]	scl2start (clocks)	scl2stop (clocks)	scl2tap (clocks)	tap2tap (clocks)
000	2	7	4	1
001	2	7	4	2
010	2	9	6	4
011	6	9	6	8
100	14	17	14	16
101	30	33	30	32
110	62	65	62	64
111	126	129	126	128

Table 48-50. I-Bus tap and prescale values

IBC[2-0]	SCL Tap (clocks)	SDA Tap (clocks)
000	5	1
001	6	1
010	7	2

Table continues on the next page...

Table 48-50. I-Bus tap and prescale values (continued)

IBC[2-0]	SCL Tap (clocks)	SDA Tap (clocks)
011	8	2
100	9	3
101	10	3
110	12	4
111	15	4

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of Table 48-49. All subsequent tap points are separated by 2^{IBC} as shown in the tap2tap column in Table 48-49. The SCL Tap is used to generate the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to the change of state of SDA that is the SDA Hold time.

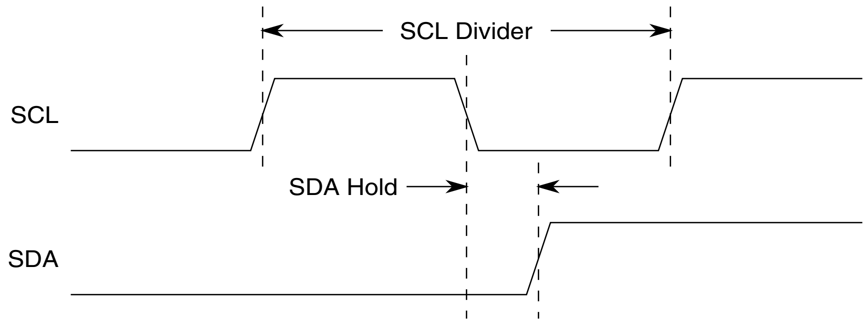

Figure 48-41. SDA Hold time

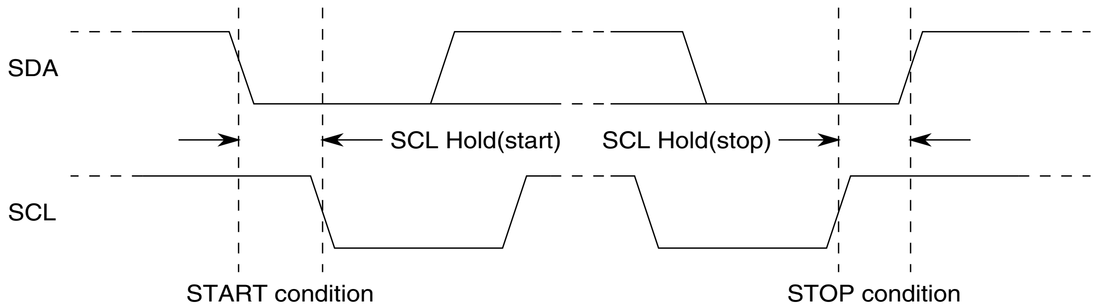

Figure 48-42. SCL Divider and SDA Hold

The equation used to generate the divider values from the IBFD bits is:

$$\text{SCL Divider} = \text{MUL} \times \{2 \times (\text{scl2tap} + [(\text{SCL\_Tap} - 1) \times \text{tap2tap}] + 2)\}$$

Figure 48-43. Equation for SCL Divider

The SDA Hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in Table 48-51. The equation used to generate the SDA Hold value from the IBFD bits is:

$$\text{SDA Hold} = \text{MUL} \times \{\text{scl2tap} + [(\text{SDA\_Tap} - 1) \times \text{tap2tap}] + 3\}$$

Figure 48-44. Equation for SDA Hold

The equations for SCL Hold values to generate the START and STOP conditions from the IBFD bits are:

$$\text{SCL Hold (start)} = \text{MUL} \times [\text{scl2start} + (\text{SCL\_Tap} - 1) \times \text{tap2tap}]$$

Figure 48-45. Equation for SCL Hold(start)

$$\text{SCL Hold (end)} = \text{MUL} \times [\text{scl2end} + (\text{SCL\_Tap} - 1) \times \text{tap2tap}]$$

Figure 48-46. Equation for SCL Hold(stop)

Table 48-51. I^{2}C divider and hold values

	IBC (hex)	SCL Divider (clocks)	SDA Hold (clocks)	SCL Hold (start)	SCL Hold (stop)

48.5.5 Interrupts

This section presents the following topics:

- Interrupt vector
- Interrupt description

48.5.5.1 Interrupt vector

The I²C module uses only one interrupt vector.

Table 48-52. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I²C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

48.5.5.2 Interrupt description

There are five types of internal interrupts in the I²C. The interrupt service routine can determine the interrupt type by reading the Status register.

I²C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I^2C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

48.5.6 IPG DEBUG mode

This mode allows CPU to debug the I^2C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I^2C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I^2C module enters IPG DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I^2C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. See the simulation result in Figure 48-47 for more details.

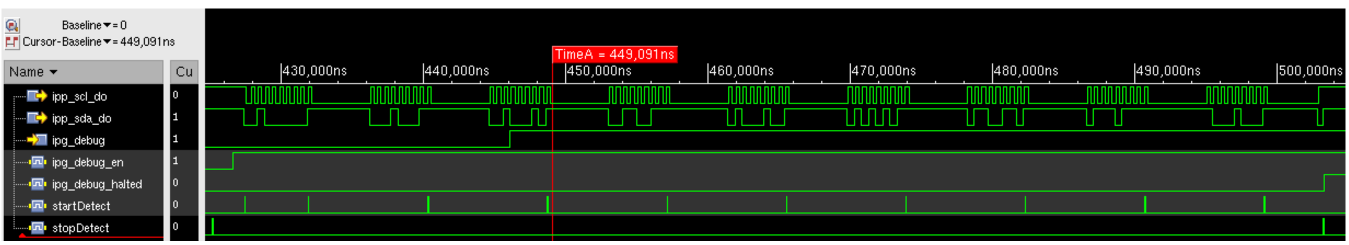

Figure 48-47. Simulation result of IPG Debug Halted in case of frame transmission

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I²C module enters IPG DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits IPG DEBUG mode, transmission or reception of the remaining bytes resumes. Please see the simulation snapshot shown in Figure 48-48 for details where the I²C is transmitting 8 bytes using DMA and IPG DEBUG mode is requested while a second byte is being transmitted. IPG DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits IPG DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

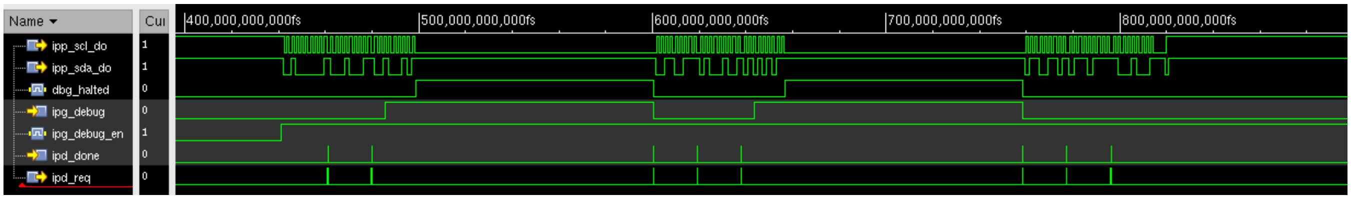

Figure 48-48. Simulation result of IPG Debug Halted in case of frame transmission using DMA

No more transaction can take place until the debug signal is de-asserted after which the I²C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I²C module has entered the IPG DEBUG mode. See the following figure for more details.

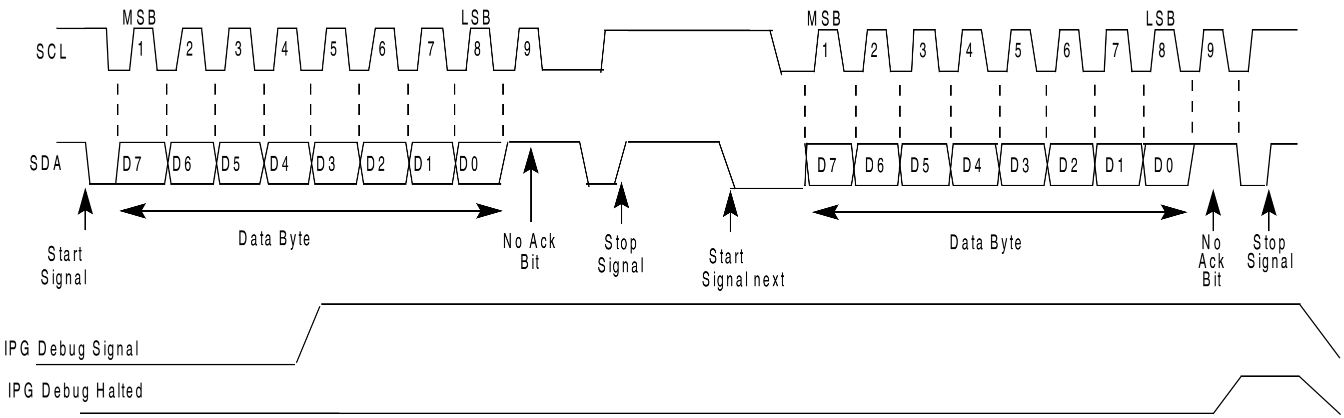

Figure 48-49. IPG DEBUG mode

The following figure shows a case of IPG DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I²C module enters IPG DEBUG mode.

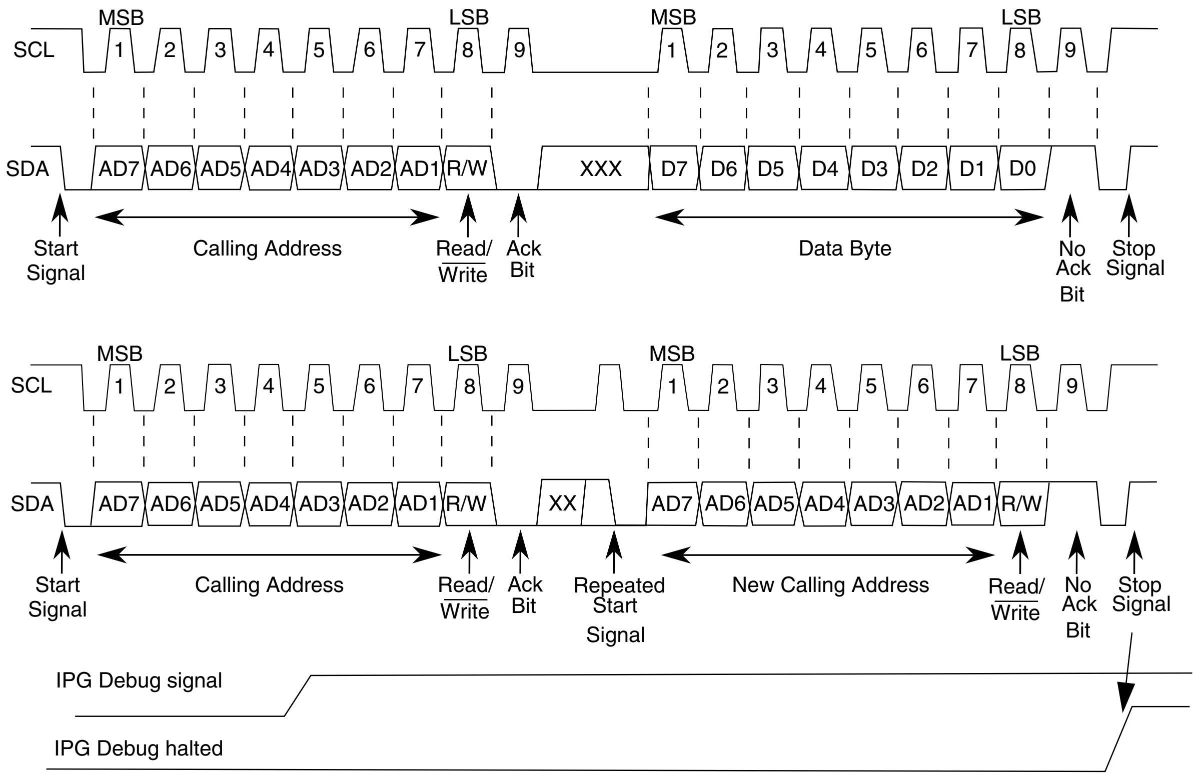

Figure 48-50. IPG debug mode with repeated start

48.5.7 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (see DMA application information). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the Initialization/application information, of this document.

48.6 Initialization/application information

This section presents the following topics:

- Recommended interrupt service flow
- General programming guidelines (for both master and slave mode)
- Programming guidelines specific to master mode
- Programming guidelines specific to slave mode
- DMA application information

48.6.1 Recommended interrupt service flow

The following figure shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

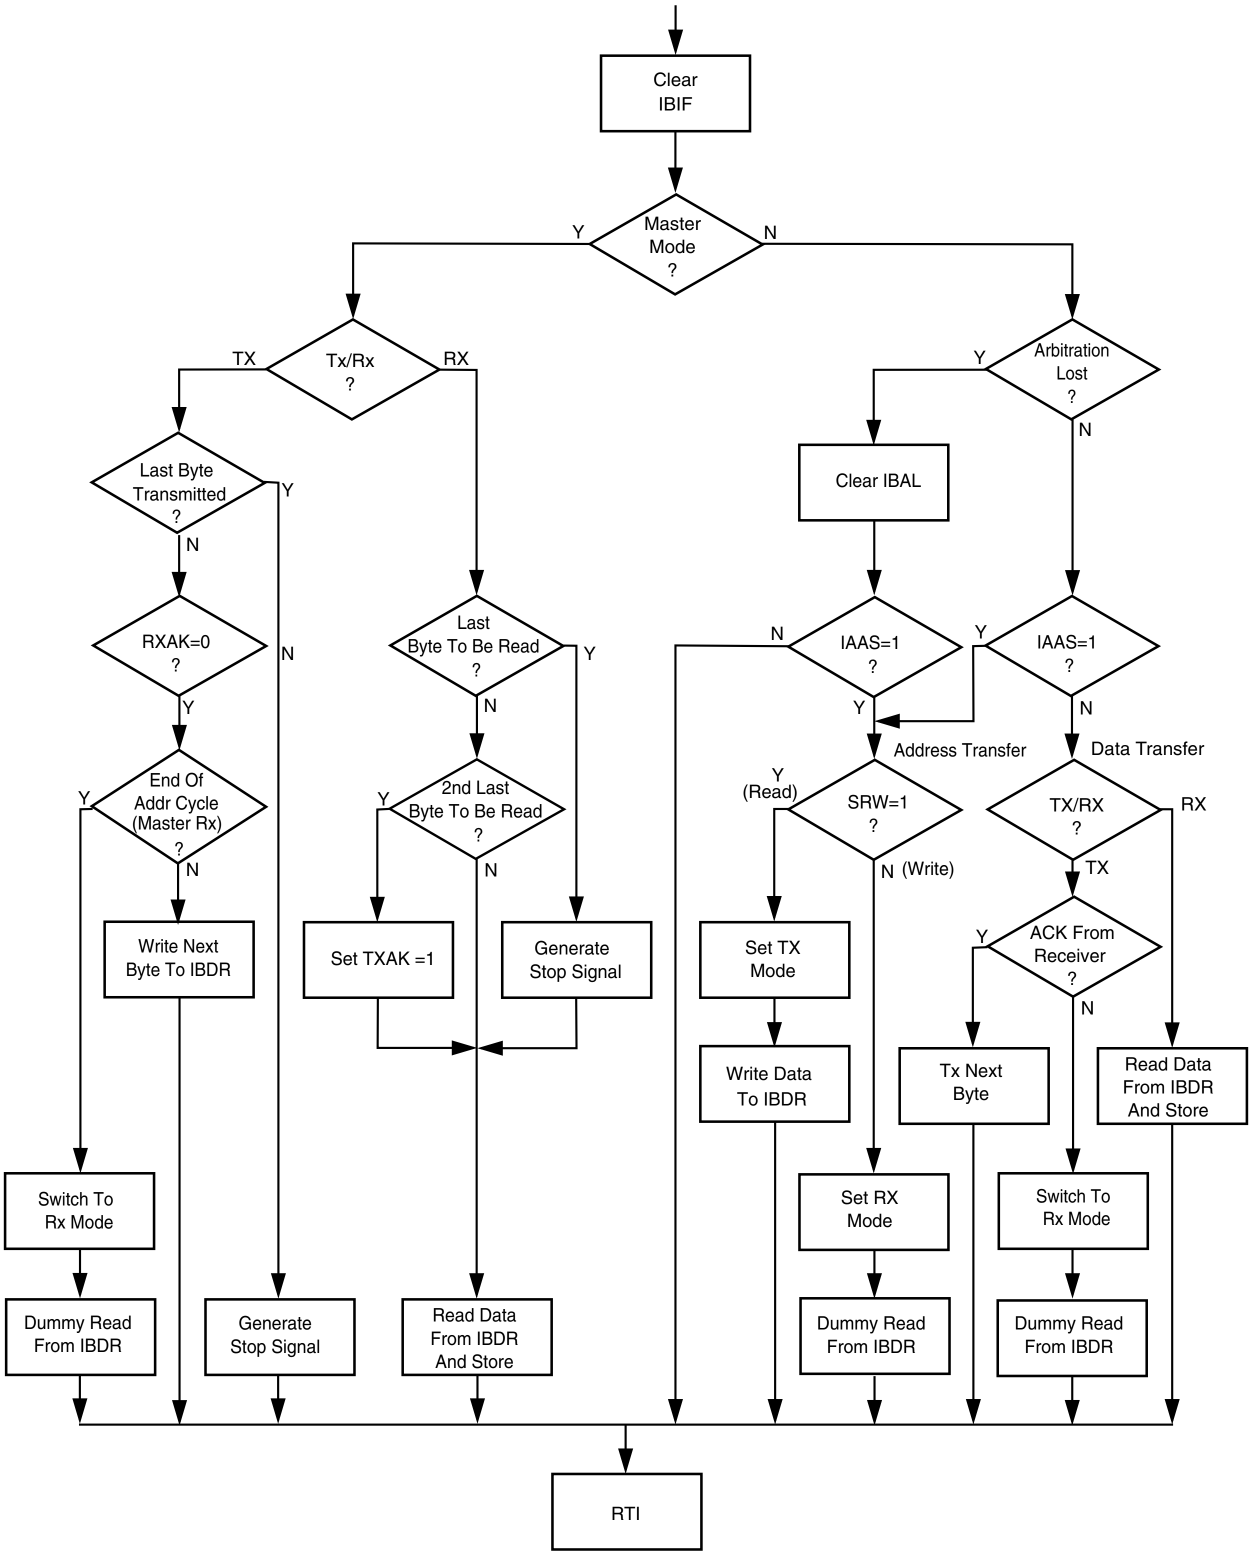

Figure 48-51. Recommended I^2C interrupt service routine flowchart

48.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I^{2}C module in both master and slave mode. It presents the following topics:

- Section 1.6.2.1, Initializing the I^{2}C module
- Software response after a transfer

48.6.2.1 Initializing the I^{2}C module

The following sequence initializes the I^{2}C module:

1. Use the IBFD register to select the required division ratio to obtain SCL frequency from system clock.
2. Use the IBAD register to define the slave address.
3. Clear the IBCR[MDIS] bit to enable the I^{2}C interface system.
4. Use the IBCR to select Master/Slave mode, Transmit/Receive mode and interrupt enable or not.
5. (Optional) Use the IBIC register to further refine the interrupt behavior.

48.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I^{2}C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I^{2}C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^2C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

48.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- Generating START
- Transmit/receive sequence
- Generating STOP
- Generating repeated START
- Loss of arbitration

48.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)// wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBVR[]Tx/Rx] = 1//master and transmit mode, that is, generate start
condition
IBDR = calling_address// send the calling address to the data register
while (bit 5, IBSR ==0)// wait in loop for IBB flag to be set
```

48.6.3.2 Transmit/receive sequence

Below sequence to be followed in case of Master Transmit (Address/Data):

1. Clear IBIF in IBSR register.
2. Write data in Data Register (IBDR).
3. TCF bit will get cleared in IBSR register when transfer is in progress.
4. TCF bit will get set in IBSR register when transfer is complete.
5. Wait for IBIF to get set in IBSR register, then read IBSR register to determine its source
    - TCF = 1 that is transfer is complete.
    - No Acknowledge condition (RXAK = 1) is found.
    - IBB = 0 that is Bus has transitioned from Busy to Idle state.
    - If IBB = 1, ignore check of Arbitration Loss (IBAL = 1).
    - Ignore Address Detect (IAAS = 1) for Master mode (valid only for Slave mode).
6. Check RXAK in IBSR for an acknowledge from slave.

Below sequence to be followed in case of Slave Receive (Address/Data):

1. Clear IBIF in IBSR register.
2. TCF bit will get cleared in IBSR register when transfer is in progress for address transfer.

3. TCF bit will get set in IBSR register when transfer is complete.
4. Wait for IBIF to get set in IBSR register. Then read IBSR register to determine its source:
   - Address Detect has occurred (IAAS = 1) — determination of Slave mode.
5. Clear IBIF.
6. Wait till TCF bit gets cleared in IBSR register (that is "Transfer under Progress" condition is reached for data transfer).
7. Wait till TCF bit gets cleared in IBSR register (proof that Transfer Completes from "Transfer under Progress" state).
8. Wait till IBIF bit gets set in IBSR register. To find its source, check if:
   - TCF = 1 that is reception is complete.
   - IBB= 0 in IBSR register i.e. Bus has transitioned from Busy to Idle state.
   - Ignore Arbitration Loss (IBAL = 1) for IBB = 1.
   - Ignore No Acknowledge condition (RXAK = 1) for receiver.
9. Read the Data Register (IBDR) to determine data received from Master.

Sequence followed in case of Slave Transmit (Steps a-d of Slave Receive for Address Detect, followed by a-f of Master Transmit for Data Transmit).

Sequence followed in case of Master Receive (Steps a-f of Master Transmit for Address dispatch, followed by e-h of Slave Receive for Data Receive)

48.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or// check to see if all data bytes have been transmitted
   (bit 0, IBSR == 1) {// or if no ACK generated
     clear bit 5, IBCR// generate stop condition
   }
else {
  IBDR = data_to_transmit// write byte of data to DATA register
    tx_count --// decrement counter
  } // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --// decrease the rx counter
if (rx_count ==1)// 2nd last byte to be read ?
 bit 3, IBCR = 1// disable ACK
 if (rx_count == 0)// last byte to be read ?
 bit 5, IBCR = 0// generate stop signal
else
data_received = IBDR// read RX data and store
```

48.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```
bit 2, IBCR = 1                                    // generate another start (restart)
IBDR == calling_address                        // transmit the calling address
```

48.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave receive mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL=1 and MS/SL=0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU and set the IBAL to indicate that the attempt to engage the bus is failed. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

48.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to

the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an "end of data" signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

48.6.5 DMA application information

The DMA interface on the I^2C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMA enable bit in the control register is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN bit in the IBCR register works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, dependant on the setting of the DMAEN bit. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.

The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place. The sections present the following topics:

- DMA mode, master transmit
- DMA mode, master reception
- Exiting DMA mode, system requirement considerations

48.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit "n" data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

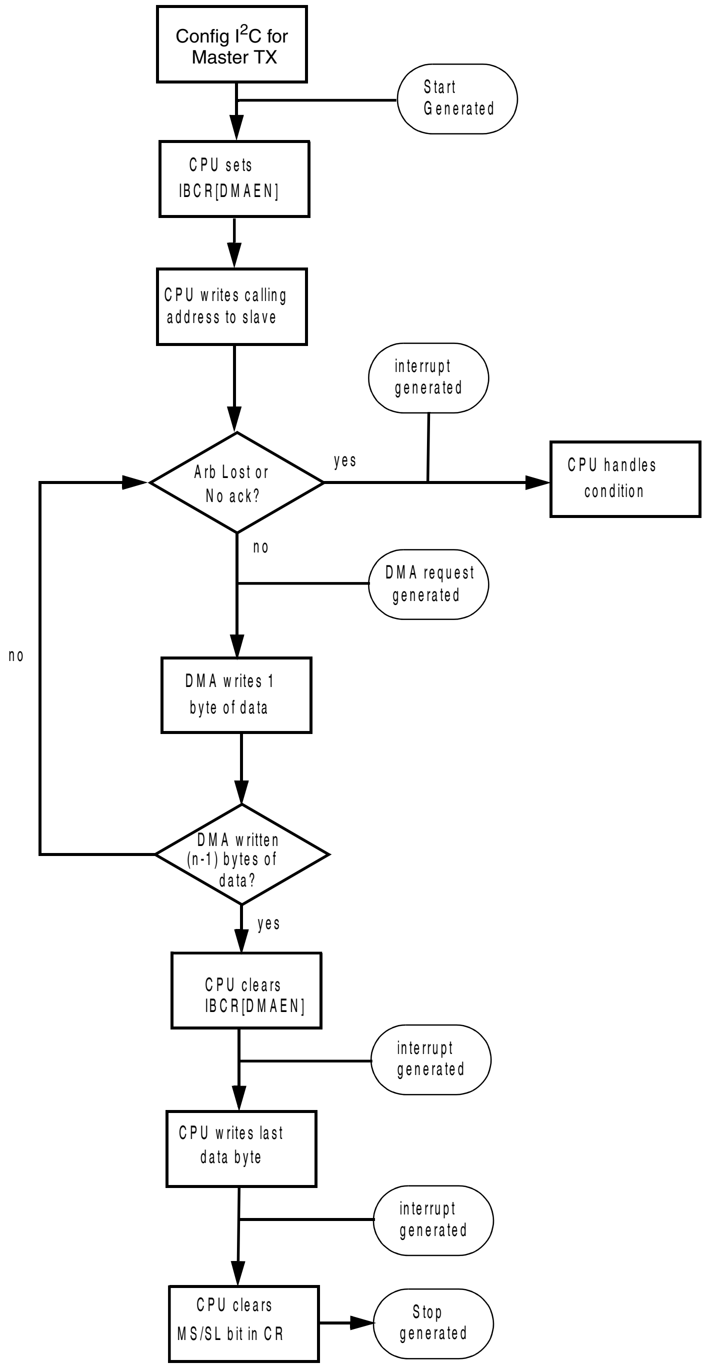

Figure 48-52. Flow-Chart of DMA mode master transmit

48.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive "n" data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

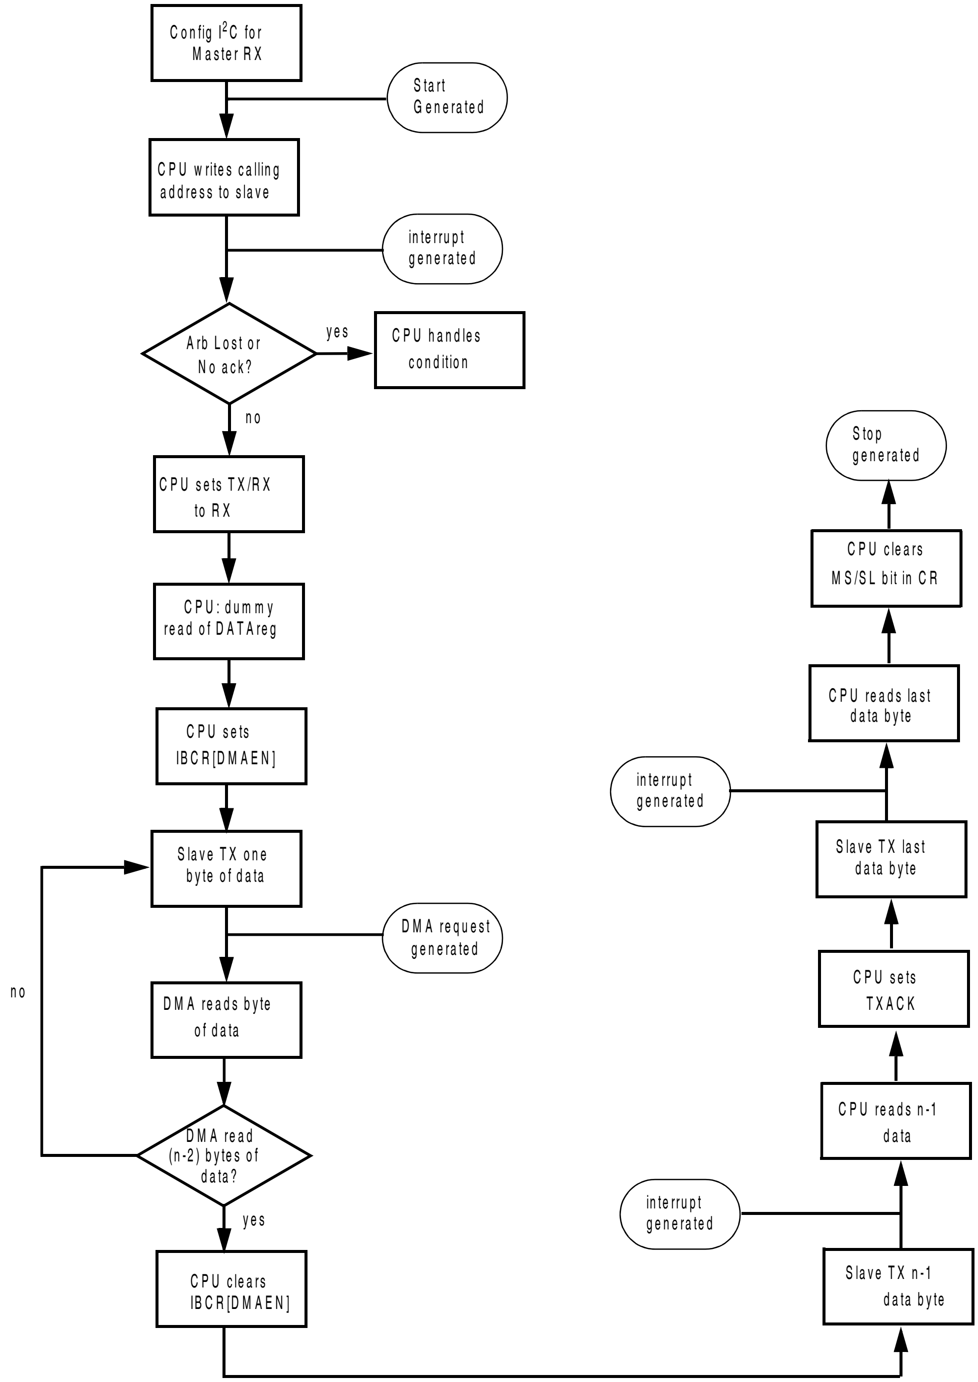

Figure 48-53. Flow-Chart of DMA mode master receive

48.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^2C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For 'fast reaction' the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

$$T_R = 8 \times T_{SCL}$$

In fast mode, with 400kbit/s, T_{SCL} is 2.5μs, so T_R is 20μs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act

accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note

The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking (if supported)

   The Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to the I^2C IBCR register to disable the DMAEN bit. This is probably the fastest system solution, but it uses two DMA channels.

Note

Here you have to make sure on system level that no higher priority DMA requests occur between the two linked TCDs as those could again create a scenario of slow reaction.

3. DMA scatter/gather process (if supported)

   The Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated. This feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the I^2C IBCR register to disable the DMAEN bit. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a "ready-for-I^2C-transfer" state. The advantage over the two other solutions is that this neither requires CPU intervention nor a 2^{nd} DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note

Here you have to make sure at system level that no higher priority DMA requests occur during the scatter/gather process, as those could again create a scenario of slow reaction.

Example latencies for a 32MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $$4 \times T_{IPI} = 4/16\,MHz = 250\,ns$$

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

  $$8 \times T_{AHD} = 8/32\,MHz = 250\,ns$$

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

Chapter 49
Universal Asynchronous Receiver/Transmitter (UART)

49.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The UART allows asynchronous serial communication with peripheral devices and CPUs.

49.1.1 Features

The UART includes the following features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- 13-bit baud rate selection with /32 fractional divide, based on the module clock frequency
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable transmitter output polarity
- Programmable receive input polarity
- Up to 14-bit break character transmission.

- 11-bit break character detection option
- Independent FIFO structure for transmit and receive
- Two receiver wakeup methods:
    - Idle line wakeup
    - Address mark wakeup
- Address match feature in the receiver to reduce address mark wakeup ISR overhead
- Ability to select MSB or LSB to be first bit on wire
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Support for ISO 7816 protocol to interface with SIM cards and smart cards
    - Support for T=0 and T=1 protocols
    - Automatic retransmission of NACK'd packets with programmable retry threshold
    - Support for 11 and 12 ETU transfers
    - Detection of initial packet and automated transfer parameter programming
    - Interrupt-driven operation with seven ISO-7816 specific interrupts:
        - Wait time violated
        - Character wait time violated
        - Block wait time violated
        - Initial frame detected
        - Transmit error threshold exceeded
        - Receive error threshold exceeded
        - Guard time violated
- Support for CEA709.1-B protocol used in building automation and home networking systems
    - Automatic clock resynchronization
    - Support for collision detection
- Interrupt-driven operation with 12 flags, not specific to ISO-7816 support

  - Transmitter data buffer at or below watermark
  - Transmission complete
  - Receiver data buffer at or above watermark
  - Idle receiver input
  - Receiver data buffer overrun
  - Receiver data buffer underflow
  - Transmit data buffer overflow
  - Noise error
  - Framing error
  - Parity error
  - Active edge on receive pin
  - LIN break detect
- Receiver framing error detection
- Hardware parity generation and checking
- 1/16 bit-time noise detection
- DMA interface

49.1.2 Modes of operation

The UART functions in the same way in all the normal modes.

It has the following low power mode:

- Stop mode

49.1.2.1 Run mode

This is the normal mode of operation.

49.1.2.2 Stop mode

The UART is inactive during Stop mode for reduced power consumption. The STOP instruction does not affect the UART register states, but the UART module clock is disabled. The UART operation resumes after an external interrupt brings the CPU out of Stop mode. Bringing the CPU out of Stop mode by reset aborts any ongoing transmission or reception and resets the UART. Entering or leaving Stop mode does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

49.2 UART signal descriptions

The UART signals are shown in the following table.

Table 49-1. UART signal descriptions

Signal	Description	I/O
CTS	Clear to send	I
$\overline{\text{RTS}}$	Request to send	O
RXD	Receive data	I
TXD	Transmit data	O
Collision	Collision detect	I

49.2.1 Detailed signal descriptions

The detailed signal descriptions of the UART are shown in the following table.

Table 49-2. UART—Detailed signal descriptions

<table>
<tr><th>Signal</th><th>I/O</th><th colspan="2">Description</th></tr>
<tr><td rowspan="3">CTS</td><td rowspan="3">I</td><td colspan="2">Clear to send. Indicates whether the UART can start transmitting data when flow control is enabled.</td></tr>
<tr><td>State meaning</td><td>Asserted—Data transmission can start.
Negated—Data transmission cannot start.</td></tr>
<tr><td>Timing</td><td>Assertion—When transmitting device's RTS asserts.
Negation—When transmitting device's RTS deasserts.</td></tr>
</table>

Table continues on the next page...

Table 49-2. UART—Detailed signal descriptions (continued)

Signal	I/O	Description	
RTS	O	Request to send. When driven by the receiver, indicates whether the UART is ready to receive data. When driven by the transmitter, can enable an external transceiver during transmission.	
		State meaning	Asserted—When driven by the receiver, ready to receive data. When driven by the transmitter, enable the external transmitter. Negated—When driven by the receiver, not ready to receive data. When driven by the transmitter, disable the external transmitter.
		Timing	Assertion—Can occur at any time; can assert asynchronously to the other input signals. Negation—Can occur at any time; can deassert asynchronously to the other input signals.
RXD	I	Receive data. Serial data input to receiver.	
		State meaning	Whether RXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.
		Timing	Sampled at a frequency determined by the module clock divided by the baud rate.
TXD	O	Transmit data. Serial data output from transmitter.	
		State meaning	Whether TXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.
		Timing	Driven at the beginning or within a bit time according to the bit encoding method along with other configuration settings. Otherwise, transmissions are independent of reception timing.
Collision	I	Collision Detect. Indicates if a collision is detected during Data Transmission.	
		State meaning	Asserted—Indicates a collision detection. UARTxCPW determines the length of this pulse for valid collision detection. Negated—No collision detected.
		Timing	Asserts asynchronously to other input signals.

49.3 Memory map and registers

This section provides a detailed description of all memory and registers.

Accessing reserved addresses within the memory map may result in unpredicatable behavior, and the contents of implemented addresses may get modified as a result of that access.

Only byte accesses are supported.

UART memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4002_7000	UART Baud Rate Registers: High (UART0_BDH)	8	R/W	00h	49.3.1/2646
4002_7001	UART Baud Rate Registers: Low (UART0_BDL)	8	R/W	04h	49.3.2/2647
